investigated since it was first described by Claude Bernard in 1859<sup>3</sup>. A number of metabolic changes resembling those which occur in human diabetes have been observed in these conditions, among them abnormally high and prolonged glucose tolerance curves, a reduced blood glucose response to insulin, a reduced glucose uptake by muscle tissue, an increase in muscle phosphorylase *a*, and a decrease in the concentration of insulin in the pancreas<sup>4,5</sup>.

The mechanisms involved in these effects are not yet clear, but the work of Randle *et al.*<sup>6</sup> and other investigators suggests that the higher rate of fatty acid metabolism in the absence of dietary carbohydrate decreases the availability of endogenous insulin.

In previous metabolic investigations, we have maintained weanling rats on the high fat, high protein diet used here, and although abnormal glucose tolerance curves were observed throughout, the animals remained in reasonably good health for up to 4 months<sup>7</sup>.

Male Sprague-Dawley rats weighing 170-200 g were fed *ad libitum* for 7 days on a diet of the following composition: 315 g high nitrogen casein; 620 g hydrogenated vegetable oil; 1 g salt mixture<sup>8</sup>; 2 g choline chloride; and 1 g vitamin mixture<sup>9</sup>. Other animals in the same weight range were fed a standard laboratory chow pellet diet. *S*-sulpho B chain was prepared from crystalline bovine insulin, reduced with reducing solution in a hot water bath, and combined with crystalline bovine serum albumin as previously described<sup>1</sup>. Only *S*-sulpho B chain prepared according to the procedure of Dixon and Wardlaw<sup>9</sup> was used in the experiments reported here. *S*-sulpho B chain prepared by the Swan procedure<sup>10</sup>, which had shown some insulin inhibitory activity in the mitochondrial assay, was ineffective *in vivo* under the conditions used.

After an 18 h fast, the animals were injected intraperitoneally with 1 ml. of 0.0062 molar cysteine-0.02 molar *tris*(hydroxymethyl)aminomethane solution, pH 8.6-8.9, containing either 1 mg of reduced B chain plus 1 mg of albumin or 1 mg of albumin alone. A second injection of either the same amount of reduced B chain and albumin or albumin alone was given after the 30 min blood sample had been taken. Blood samples (0.1 ml.) were taken from the heart under light ether anaesthesia before the first injection and 30, 60 and 90 min thereafter. Blood glucose levels were determined by 'Technicon AutoAnalyzer' method N-9.

The results are shown in Table 1. The hyperglycaemia previously observed in normal rats<sup>1</sup> was again seen in this experiment. In the animals fed on chow, the increases in blood sugar over the control values at 30, 60 and 90 min for the group treated with reduced B chain-albumin were 22, 31 and 21 per cent respectively, in comparison with the increases of 6, 7 and 13 per cent respectively for the group treated with albumin at the same intervals of time. The Student *t* test shows a significant difference at 30 min and a highly significant difference at 60 min between the two groups. The difference at 90 min is not significant, and probably reflects an offsetting of the reduced B chain inhibition by an increased secretion of insulin.

In the animals on the high fat, high protein diet the increases in blood glucose in the group given reduced B chain-albumin, calculated from the control values at 30, 60 and 90 min, were 49, 72 and 42 per cent respectively, in comparison with increases of 11, 6 and 12.5 per cent respectively for the group treated with albumin. The differences

between the reduced B chain-albumin and the albumin groups were highly significant at 30 and 60 min and significant at 90 min.

An explanation for these results other than inhibition of insulin activity by B chain would be that the preparation injected produced hyperglycaemia through a non-specific effect such as adrenal stimulation. Such an effect is unlikely, however, because the injection of B chain alone, *S*-sulpho B chain with albumin, or B chain-albumin from which the reducing solution had been dialysed did not produce hyperglycaemia.

The results suggest that the B chain does not have the configuration or chemical properties required for an inhibitory effect unless it is actively maintained in the reduced state and complexed with an agent such as albumin. When these conditions are met, and when a sufficiently large excess is given to provide for oxidation and other modes of attrition which can occur after injection, the anti-insulin effect can readily be demonstrated.

The enhanced inhibitory effect of insulin B chain in the diabetes-like state induced by the high fat, high protein diet seems to add weight to the hypothesis that this mechanism is important in true diabetes.

We thank Dr. Rudolph Tomarelli for preparing the diets and for advice, Mr. Robert Whitley for blood glucose analyses, and Mr. William Bechmann and Miss Kathleen Rowan for valuable technical assistance.

### Histochemical Localization of Intestinal Disaccharidases: Application to Peroral Biopsy Specimens

THIS communication describes a technique for localizing intestinal disaccharidases developed from that of Dahlqvist and Brun<sup>1</sup>. Intestinal biopsies were obtained by a multi-purpose suction biopsy tube<sup>2</sup> from four normal children and five patients with sucrose and isomaltose "intolerance". Intestinal specimens from rats and guinea-pigs have also been investigated by the same procedure. The biopsies and animal tissues were rapidly frozen and stored at -25°. Sections from 8 $\mu$  were cut in a cryostat, mounted on coverslips and fixed in cold acetone for 15 min.

The chromogenic reagent (I) was prepared by a solution in phosphate buffer (pH 6.5; 0.1 molar) of the following reagents: 5 mg/ml. gelatine; 0.05 mg/ml. phenazine methosulphate; 0.33 mg/ml. tetranitroblue-tetrazolium (TNBT); and 0.2 mg/ml. glucose oxidase.

The substrate solutions (II) were made up with 100 mg of saccharose, lactose or palatinose per ml. of distilled water. When maltose and trehalose were used as substrates, the concentrations were 25 mg and 50 mg per ml. respectively.

The mounted sections were placed on the flat lid of a tissue culture vessel and 0.05 ml. of a concentrated solution of glucose oxidase (4 mg/ml. phosphate buffer pH 6.5, 0.1 molar) were deposited on each. They were then covered with a piece of thin rapid filter paper, previously cut to the shape of the lid and moistened with 0.2 ml. of the chromogenic reagent (I). The vessel containing 1 ml. of chromogenic reagent (I) and 0.1 ml. (0.2 ml. for lactose) of the appropriate substrate solution (II) was closed by the cover to which the coverslip and filter paper remained attached. The vessel was then sealed with silicone grease, shaken vigorously and turned upside down.

Incubation for 3–6 h at 37° generally gave a suitable brown stain. Thereafter, the sections were washed thoroughly in hot water (45°) and mounted in 'Apathy' syrup.

Control sections were incubated in a staining solution from which the substrate had been either omitted or replaced by melibiose, a non-hydrolysable disaccharide.

Some sections were treated before incubation with sulphhydryl inhibitors such as *p*-chloromercuribenzoate (PCMB) in order to inhibit the non-specific staining of sulphhydryl compounds. These sections were dipped for 15 min in phosphate buffer at pH 7.4 containing 0.0025 molar PCMB and then washed in phosphate buffer at pH 6.5.

Fig. 1. Maltase activity in normal duodenal biopsy. ( $\times c. 165$ .)

Our modifications to the original procedure of Dahlqvist and Brun were devised to reduce diffusion of glucose as far as possible. This was achieved by increasing the concentration of glucose oxidase and by using a filter paper which maintains a high glucose oxidase concentration close to the site of enzyme activity. Otherwise, the filter paper moistened with gelatine solution (I) retains a superficial precipitate which results from the unavoidable diffusion of a small amount of glucose. Finally, the use of TNBT instead of nitroBT gives an improved staining picture because the precipitate of TNBT formazan is finer and far more localized<sup>3</sup>.

The results of this histochemical procedure are similar in human normal duodenal mucosa, as well as in guinea-pig mucosa, whether maltose, saccharose or palatinose is used as the substrate. The reaction, however, is stronger with maltose. The precipitate is accurately localized in the brush border of the villous epithelial cells whereas the staining is absent from or weak in the cytoplasm (Fig. 1). There is no stain in the crypts. Precipitate is found in some cells of the lamina propria. In the muscularis mucosae and the submucosal vessels, a faint staining is in all likelihood non-specific since it does not occur after treatment by PCMB.

Fig. 2. Normal trehalase activity. ( $\times c. 65$ .)

The activity of trehalase is also intense in the brush border, but the reaction is rather localized near the tip of the villi (Fig. 2). With lactose as the substrate, a stain is obtained not only in the brush border but also in the apical cytoplasm of the villous epithelial cells (Fig. 3).

Control sections of human and guinea-pig material incubated without substrate give consistent negative results, whereas rat intestinal sections incubated in the same manner develop a stain throughout the cytoplasm of the epithelial cells. This non-specific staining is blocked by previous treatment with PCMB.

Sections from tissue without disaccharidase activities always failed to react significantly. This result excludes any interference of disaccharidases which may contaminate the glucose oxidase preparations in the staining process<sup>1</sup>.

Intestinal biopsies of patients with congenital sucrose and isomaltose "intolerance", have normal trehalase and lactase activities, whereas they react weakly with maltose and not at all with saccharose and palatinose. These results are in close agreement with the quantitative enzyme determinations in tissue homogenate<sup>4</sup>.

Our improved staining method can thus be applied to the demonstration and localization of disaccharidase activities in both normal and pathological intestinal biopsies. This technique shows particularly that the disaccharides splitting enzymes are primarily if not

Fig. 3. Normal lactase activity. ( $\times c. 265$ .)

exclusively localized in the brush border in accord with the biochemical findings<sup>5,6</sup>.

Detailed reports will be published elsewhere.

### Composition of Membranous Tissues obtained from Tendon and Skin

THE presence of a sheath surrounding the collagen fibrils of skin and tendon was first shown histologically by Kaye<sup>1</sup> in 1925, and its restrictive effects on swelling and eventual rupture were demonstrated by Jordan Lloyd and Marriott<sup>2</sup>. Recently, Kwon, Mason and Rigby<sup>3</sup> have again directed attention to the presence of this sheath in tail tendon and have pointed out its probable effect on hydrothermal shrinkage as well as on swelling.

A plentiful supply of kangaroo tail tendons has made it possible to isolate sufficient of the sheath to carry out an amino-acid analysis and limited histological and electron microscope examination. The tendons were removed from the tails in Australia, washed several times in 5 per cent sodium chloride, then in water, and dehydrated in acetone for transport. After resoaking in water, the tendons were swollen in 0.1 molar acetic acid, and by splitting the sheath longitudinally down one side it was possible to remove it from the bulk of the tendon fibres.

The membrane stained with acidic and basic dyes in a similar manner to collagen and there were indications of a very fine fibrillar structure. Numerous cells could be seen, but there was no evidence of the presence of elastin. A few larger collagen fibrils were visible on the surface but were not included in the ground structure of the membrane; these presumably arise from the tendon proper. Direct and microscopical observations both indicated that these extraneous fibrils represented less than 10 per cent of the total material. Electron micrographs were typical of connective tissue systems, showing a few fibrils with characteristic collagen banding, together with a generalized matrix or continuum<sup>4</sup>.

A sample of sheath (30 mg) was hydrolysed with 5 ml. 6 normal hydrochloric acid at 105° C for 18 h. The amino-acid composition was determined using an automatic analyser and the elution procedure described by Hannig<sup>5</sup>. Hydroxyproline was determined directly by the method of Stegemann<sup>6</sup> modified for use with the 'Technicon' autoanalyser.

The amino-acid composition of the sheath is clearly different from that of the tendon as a whole. The hydroxyproline content indicates the presence of about 65 per cent collagen, more than can be accounted for by contamination with collagen fibrils from the tendon, together with about 35 per cent of a non-collagenous protein. Some indication of the composition of this non-collagenous fraction can be obtained by subtracting the contribution due to the collagen. The results so obtained expressed in terms of residues per 1,000 total residues are given in Table 1. The protein shows certain resemblances to other non-collagenous protein fractions obtained from collagenous tissues, for example, the protein extracted from skin by dilute alkali<sup>7</sup> and the protein of the chondroitin sulphate complex of cartilage<sup>8</sup>. It differs in containing an appre-

\* Corrected on the basis that the hydroxyproline nitrogen in collagen represents 8.22 per cent of the total nitrogen and that all hydroxyproline arises from collagen<sup>10</sup>.

ciable amount of cystine, which no doubt accounts for its greater insolubility compared with collagen. The rather low recovery of nitrogen as amino-acids and the low nitrogen content—15–16 per cent on dry weight—suggest the presence of mucoid material. It seems probable, therefore, that the tendon sheath, like renal reticulin<sup>9</sup>, is composed of very fine collagen fibrils, but in this case embedded in a matrix of a non-collagenous type protein, probably a mucoprotein, rather than in predominantly lipid material.

A membranous tissue can also be peeled off from the underside of many types of skin. Some of this material removed from skin treated with alkali was also examined. It appears to consist of collagen together with about 16 per cent of another protein. The composition of this protein is also similar to that of the tendon sheath, but differs in the apparent absence of proline and in its high contents of leucine and valine. In spite of the alkali treatment, it still contained between 0.8 and 1 per cent of hexosamine on a dry weight basis.

It would seem, therefore, that there is a variety of membranous structures in collagenous tissues which consist predominantly of very fine collagen fibrils embedded in a matrix containing non-collagenous protein, mucoid and in some cases lipid material. The function of such sheaths is presumably to regulate penetration, swelling, and generally to maintain strength and stability. Certainly *in vitro* the presence of such sheaths plays an important part in such processes.

We thank Miss B. M. Haines for histological examination, and Dr. R. Reed of the University of Leeds for electron microscope examination. We also thank the staff of the Research Station of the Department of Agriculture and Stock, Queensland, for the preparation of the kangaroo tail tendons.

## PATHOLOGY

### Inhibition of Tumour Formation with Adenovirus 12 Tumour Cells in Hamsters Immunized with Various Adenoviruses

TUMOUR production by adenovirus type 12 in newborn hamsters inoculated subcutaneously has been confirmed in several laboratories<sup>1,2</sup>. Eddy and co-workers<sup>3</sup> found inhibition of this tumour production in hamsters repeatedly inoculated with live adenovirus type 12 during the incubation period of tumour formation. More recently, Peries *et al.*<sup>4</sup> demonstrated inhibition of the formation of adenovirus 12 induced tumours in hamsters inoculated subcutaneously with a live heterotypic virus, adenovirus type 5. No inhibition occurred, however, when killed adenovirus type 5 was used. The mechanism of tumour inhibition in both sets of experiments was not established.

We have studied tumour formation in Syrian hamsters (*Mesocricetus auratus*) inoculated with tissue culture cells (*H212* line) derived in this laboratory from a hamster tumour induced by adenovirus type 12. This communication describes the inhibition of *H212* cell-induced tumours in hamsters immunized with either homotypic or heterotypic adenoviruses.

The *H212* cell line was established from a primary transplant of a hamster tumour developing 65 days after subcutaneous inoculation of the "Huie" strain of adenovirus type 12 cultivated in human embryo kidney cells. These cells have been grown *in vitro* for 2 years through ninety-nine serial subcultures and their cultivation and cellular characteristics will be reported elsewhere. *H212* cells resemble hamster cells transformed by adenovirus type 12 described by other workers<sup>5</sup> in morphology, freedom from infective adenovirus and the continuous production of virus-specific antigens<sup>6,7</sup>. These cells induce progressively growing tumours at the site of inoculation in hamsters. In contrast to adenovirus 12 induced tumours, which only develop after the inoculation of newborn animals, *H212* cells induce tumours in a proportion of hamsters aged 3 months or more.

The adenovirus strains\* used for the preparation of antigens for immunization experiments were grown in either human embryo kidney (*HEK*) or HeLa cell cultures maintained in Eagle's basal medium with 2 per cent inactivated calf serum. Infected cell cultures at a late stage of virus cytopathic effect were frozen and thawed three times and the fluids were centrifuged at 800*g* for 20 min to remove cell debris before storage at  $-20^{\circ}\text{C}$ . In some experiments inactivated adenovirus antigens were prepared by treating the fluids with formalin using the method of Hilleman *et al.*<sup>8</sup>. The live antigens were tested for tumour-inducing capacity by subcutaneous inoculation into hamsters at the same age as those used in the immunization experiments. No tumours developed in animals inoculated with the live virus antigens only.

Hamsters from a closed colony of random bred animals were used in the immunization experiments. Batches of animals of the same age were immunized by four subcutaneous injections of 0.2 ml. of the various antigens at 10, 14, 21 and 28 days of age. As a control to antigens containing virus, some batches of animals were not immunized while others received virus-free cultures of *HEK* or HeLa cells.

That the virus antigens had induced the formation of antibody was shown by tests for specific homologous neutralization using sera collected from animals at the time of challenge. At 33–35 days of age the mothers of immunized or control animals were removed and their litters randomized before challenge with *H212* cells. Groups of randomized animals were inoculated subcutaneously with a range of serial ten-fold dilutions of cells (between  $3 \times 10^3$  and  $3 \times 10^6$  cells per hamster) and the hamsters observed for tumour formation for the following 180 days.

Table 1 shows the proportions of hamsters developing tumours in the groups immunized with adenovirus and the control groups. In five groups of hamsters which were not immunized, or received virus-free *HEK* or HeLa cells

\* U.S.A. prototype strains kindly supplied by Dr. M. S. Pereira, Virus Reference Laboratory, Central Public Health Laboratory, Colindale Avenue, London.

† No. of hamsters developing tumours  
No. inoculated with *H212* cells

‡ Experiments with significant tumour inhibition at the 5 per cent probability level ( $P < 0.05$ ).

(experiments 1, 2 and 4), the proportion of animals developing tumours was between 41 and 58 per cent. In experiment 3, however, a lower incidence of tumours was formed. In all experiments a lower proportion of hamsters immunized with adenovirus developed tumours compared with that in the control groups. This trend of tumour inhibition was significant (Yates's corrected  $\chi^2$  test) in the groups of hamsters immunized with inactivated adenovirus type 5 ( $P < 0.001$ ), live adenovirus type 2 grown in HEK cells ( $P < 0.05$ ) and live adenovirus type 7 grown in HEK or HeLa cells ( $P = < 0.01$ ). Tumour inhibition after immunization with heterotypic adenoviruses was unexpected and, for adenoviruses types 2, 5 and 7, was greater than that in animals immunized with homotypic adenovirus type 12.

For adenovirus types 5 and 7, live antigens prepared in HEK and HeLa cells were compared (experiment 4). With adenovirus type 7 a similar degree of inhibition of tumour formation was noted for antigens prepared in both types of culture, while adenovirus type 5 grown in HEK cells produced a greater degree of inhibition than antigen grown in HeLa cells. Tumour inhibition appeared to depend on the presence of adenovirus antigen, since in control animals inoculated with virus-free HEK or HeLa cells there was no significant inhibition of tumour formation.

These results are of interest in relation to the demonstration by Huebner *et al.*<sup>9</sup> of nonvirion "neoantigens" in hamster tumours induced by adenovirus type 12. Such antigens are shared by adenovirus types 12, 18 and 31, but cross-reacting "neoantigens" were not demonstrated for adenovirus types 1, 2, 5 and 7. Further work is in progress to determine whether the tumour inhibition described here is associated with soluble group specific adenovirus antigens, antigens resembling "neoantigens" or adenovirus particle antigens. In addition it is of interest to determine whether immunization with heterotypic adenoviruses can inhibit tumour formation in hamsters inoculated with adenovirus type 12 when newborn.

We thank Professor C. P. Beattie and Professor C. H. Stuart-Harris for their help and encouragement in this study. We also thank the British Empire Cancer Campaign for Research for a grant in support of this project.

### Urinary Phenols in Melanoma

RECENT observations<sup>1</sup> on the urinary metabolites of 3:4-dihydroxyphenylalanine (DOPA) have prompted us to examine the excretion of phenolic acids in five patients with malignant melanoma, three of whom had hepatic metastases and melanuria and two only locally recurrent cutaneous and lymphatic lesions; all were on uncontrolled

diets. Phenolic acids were examined chromatographically<sup>2</sup> in both hydrolysed and unhydrolysed urines in all cases.

No abnormality was found in the two patients with clinically localized disease. In addition to a few unidentified spots, the following phenolic acids were found to be excreted in abnormally high quantities by all three subjects with generalized melanoma: 4-hydroxy-3-methoxyphenyllactic<sup>1</sup> (VLA), 4-hydroxy-3-methoxyphenylpyruvic<sup>1</sup> (VPA), 4-hydroxy-3-methoxyphenylacetic (HVA), *p*-hydroxyphenyllactic (*p*-HPLA), *p*-hydroxyphenylpyruvic (*p*-HPPA) and, probably, *p*-hydroxyphenylacetic acids. In two of these cases the urines were examined further: both patients showed a large excretion of indole melano-gens; examination for urinary amines chromatographically showed high excretion of 3-methoxytyramine in each subject although excretions of metanephrine and normetanephrine were normal. In routine amino-acid chromatograms neither 4-hydroxy-3-methoxyphenylalanine<sup>3</sup> nor DOPA was detected and tyrosine excretion was not abnormal.

Duchon and Gregora<sup>4</sup> had previously examined urines from five similar subjects. In addition to HVA they noted that three other substances were excreted in large amounts. Two of these, spots Nos. 2 and 3 as described by these authors, can now be identified with virtual certainty as VLA and *p*-HPLA, respectively. The remaining spot, No. 4, which seemed to be indolic, resembles one which appeared on our chromatograms as a mixture of overlapping unidentified substances. The overall pattern of phenolic acid excretion in generalized melanoma thus seems to be rather constant and characteristic of the disease. In view of the quantity and wide variety of phenolic and indolic derivatives of DOPA excreted by each patient it can safely be assumed that the melanoma tumour tissue produced large amounts of this amino-acid.

Two aspects of the phenolic acid pattern in melanuria appear to be of particular interest. First is the excretion of large amounts of tyrosine metabolites. Both *p*-HPPA<sup>5</sup> and *p*-HPLA<sup>6</sup> have been reported to be excreted in abnormal quantities in many pathological conditions. It is usually accepted that such "tyrosylurias" can be attributed to an impairment in the oxidation of *p*-HPPA as a result of the absence of, or inhibition of, the necessary *p*-HPPA hydroxylase (for a recent summary of tyrosyluria, see ref. 7). In generalized melanoma the impairment may indicate an inadequate supply of the enzyme because of reduction in liver tissue as a result of tumour infiltration.

The second point of interest concerns the relative amounts of the various DOPA metabolites excreted. Normal urines contain relatively substantial quantities of HVA, but VPA is detectable in much smaller amounts only as a highly fluorescent hydantoin derivative<sup>1</sup> and VLA has not been detected as yet. Our subjects showed only moderately increased excretions of HVA, as did those of Duchon and Gregora<sup>4</sup>. By contrast, excretions of VPA and VLA were much more striking. The formation of HVA from DOPA could be preceded by either decarboxylation of amino-acid to amine or transamination of amino-acid to pyruvic acid. No direct evidence is available to support the second process, but the first is indicated by the increased excretion of the intermediate 3-methoxytyramine. Transamination (or the unlikely but equivalent oxidative deamination) must, however, precede the formation of VPA and probably that of VLA which is most likely derived from pyruvic acid by reduction. These findings suggest that in melanoma there is a shift in the metabolism of DOPA towards products derived by transamination rather than by decarboxylation. Although difficult to pinpoint because of the complications arising from the possibility of *O*-methylation occurring at any point along the sequences from DOPA to the various methylated derivatives, it seems most likely that an impairment occurs somewhere in the normal metabolism of DOPA as well as in that of tyrosine. A high excretion of VPA would result if oxidation of pyruvic acid (to sub-

stituted phenylacetic acid or to undetected, possibly aliphatic, metabolites) were impaired; in this event a shift towards transamination would only be apparent. On the other hand a real shift would result if decarboxylation were impaired, thus forcing metabolism through the transamination pathway.

Such an impairment might again result as a consequence of liver damage. We wish to direct attention, however, to the possibility that the metabolic pathways of tyrosine and DOPA may not be entirely independent and might well be subject to mutual interference. Enzyme systems participating in the metabolism of aromatic amino-acids seem frequently to be susceptible to inhibition by compounds structurally related to their substrates. Aromatic pyruvic and lactic acids seem to be particularly potent in this respect and members of this group have been shown to inhibit the activities of *p*-HPPA oxidase<sup>8</sup>, tyrosine transaminase<sup>9</sup> and DOPA decarboxylase<sup>10</sup>. In melanoma any of numerous inhibitory effects might be operative and these rather than, or in addition to, liver damage might account for the findings.

Although the data are as yet meagre, other observations suggest that abnormalities in the metabolisms of tyrosine and DOPA may be closely linked. It has been previously reported<sup>1</sup> that detectable quantities of urinary VLA are usually associated with a high excretion of *p*-HPLA. Furthermore, one of the most puzzling features of Medes's classical case of tyrosinosis<sup>11</sup> is the claim that the subject excreted DOPA when fed tyrosine and tyrosine and *p*-HPPA when fed DOPA. Although the experimental data cannot be accepted unreservedly because of the problems created by dietary control, identity of the DOPA isolated and apparent absence of DOPA metabolites, an explanation in terms of mutual interference seems as attractive as any other. It may be noted that if our speculations on these lines are correct, then simultaneously increased excretion of DOPA and tyrosine metabolites would not necessarily imply increased production of DOPA, although this undoubtedly occurs in melanoma.

## Spontaneous Tumours in Howler Monkeys

DURING 1965 we conducted post-mortem examinations on 292 free ranging howler monkeys (*Alouatta caraya*, Humboldt, 1812)<sup>1</sup> and found fourteen tumours (Table 1). In a recent review of spontaneous malignant tumours in non-human primates, Kent<sup>2</sup> reported forty-nine cases in eighteen species, but none were found in *Alouatta*. Houser *et al.*<sup>3</sup> have found benign adrenal adenomas in *Alouatta villosa* of Panama.

In *Alouatta caraya* we found cortical adenomas of the adrenal glands in eleven animals. The neoplasms ranged

in size from 1 to 20 mm, and in all cases only one node was found. The tumours were encapsulated by a fibrous capsule and occasionally compressed the adjacent adrenal cortical tissue. The cells of these adenomas were arranged in a columnar pattern, similar to that of the zona fasciculata, and did not show pleomorphism or giant nuclei; occasional normal mitotic figures were present.

A testicular seminoma was found in one adult male weighing 5 kg (ref. 4). This tumour consisted of a solid whitish grey node, measuring 8 mm in diameter, which had no sharp demarcation from the normal testicular tissue. Microscopically, this case presented the monocellularity, the stromal pattern and the focal lymphocytic infiltration which are commonly found in human seminomas. The tumour cells were moderately large and polyhedral with hyperchromatic nuclei. There was moderate mitotic activity; in the peripheral portion of the neoplasm atypical mitotic figures as well as necrotic seminiferous tubules were observed. No metastatic lesions were observed in the abdominal and inguinal lymph nodes, or in the abdominal and thoracic viscera, nor were metastatic lesions seen in survey films of the skeleton. This is the fourth malignant testicular tumour on record and the second seminoma found in non-human primates.

Table 1. TUMOURS FOUND IN WILD HOWLER MONKEYS (*Alouatta caraya*)

Group	Number of animals		Males	Females
	♂	♀		
Prepuberal	43	20	0	0
Postpuberal	131	98	Seminoma (1) Alveolar lung carcinoma (1) Adrenal adenomas (5)	Adrenal adenomas (6) Renal adenoma (1)

A type of lung neoplasia found in one adult male howler monkey has not been previously reported in non-human primates. The tumour was believed to be an alveolar carcinoma; it was situated in a peripheral location and was classified as a nodular form. The alveolar walls were lined by a single regular layer of cuboid epithelial cells, and mucin-secreting activity was detected. No metastasis was found.

A renal adenoma was found in the medullary portion of the kidney of one adult female. The tumour, approximately 3 mm in size, showed tubules and cysts, lined by epithelial cells. No papillary projections were observed.

Our findings raise a number of questions. We found no neoplasms in prepuberal animals, and this is in accordance with findings of other observers with other non-human primates in studies dealing mainly with young animals. Adrenal adenomas similar to those observed in *Alouatta caraya* have also been described in *Alouatta villosa*<sup>3</sup>; it is interesting that these tumours are frequent in this genus as in man but not in the common laboratory primate, the rhesus monkey. The overall incidence of malignant tumours in the present series is less than 1 per cent, but the occurrence of two cancers in 131 adult males, which is more than one would expect in a human population of comparable age, raises the possibility that this species may be unusually prone to cancer. It also seems to be higher than the percentages reported by others in other non-human primates.

I thank Dr. M. R. Malinow who conducted the field trip that made this study possible. I also thank the U.S. National Institutes of Health for a grant.

## HAEMATOLOGY

## Basic Protein of Normal Human Plasma

BASIC low molecular weight proteins of normal human blood, designated as  $B_1$  and  $B_2$ , were recently discovered by Takahashi and Schmid<sup>1</sup>. Acidic and neutral low molecular weight serum proteins and peptides, however, have been known for many years<sup>2-4</sup>. In the present report the purification and partial characterization of one of the basic proteins,  $B_2$ , are described.

Fraction VI of pooled normal human plasma was chromatographed on a DEAE-cellulose column at pH 5.5 and  $\Gamma/2$  0.005 (ref. 5). The resulting effluent was passed subsequently through a CM-cellulose column at the same pH and ionic strength to adsorb and concentrate the proteins from this solution. Fractional elution of the second column gave the  $3S \gamma_1$  (ref. 5) and  $2S \gamma_2$  (ref. 6) globulins and the mentioned basic components. The basic compounds were further purified on a DEAE-Sephadex A-50' column at pH 8.4 and  $\Gamma/2$  0.005. Final purification was achieved by chromatography on a hydroxylapatite column at pH 6.8. The resulting  $B_2$ -preparation revealed a single component on ultracentrifugation and starch gel electrophoresis at pH 8.6 (Fig. 1).

Fig. 1. Starch gel electrophoresis of  $B_2$  in pH 8.6,  $\Gamma/2$  0.01 borate buffer. Amido black was used as stain and lysozyme as reference. The protein moved toward the cathode (—).

The basic protein,  $B_2$ , was characterized in terms of some of its major physical chemical and chemical properties. Its molecular weight determined by the Yphantis procedure<sup>7</sup> was found to be approximately 9,000. On ultracentrifugation  $B_2$  sedimented at the rate of  $1.3S$ . The isoelectric point of this protein was estimated to be between pH 10.0 and 10.5. Ultra-violet absorption (Fig. 2) between 250 and 290 m $\mu$  revealed a maximum that indicated a very low content of tyrosine and/or tryptophan. Chemical analysis of  $B_2$  showed that its polypeptide moiety accounted for the total weight. Independent measurements confirmed the lack of neutral hexoses, hexosamines, and sialic acid.

We thank Dr. J. McComb, Mr. L. Larsen and their co-workers of the Division of Biologic Laboratories at Massachusetts Department of Health. This investigation

Fig. 2. Absorption curves of  $B_2$  measured at pH 6 and 13, respectively.

was supported by grants from the National Institute of General Medical Sciences, U.S. Public Health Service.

Decrease in the Concentration of Haemoglobin  $A_2$  during Erythroleukaemia

DURING the past decade there have been several descriptions of abnormal haemoglobin in leukaemia<sup>1-4</sup>. The earliest reports emphasized the increase of foetal haemoglobin content in some cases of leukaemia in children and adults<sup>1-3</sup>. The occurrence of haemoglobin H in cases of erythroleukaemia and atypical chronic myeloid leukaemia was also reported<sup>4</sup>. In these cases no alteration in the level of the normal minor haemoglobin fraction, haemoglobin  $A_2$ , was noted. We have investigated an erythroleukaemic patient with a very low level of haemoglobin  $A_2$  which developed in the course of leukaemia.

A 63 year old man, first seen in 1963, had clinical and haematological findings of subacute erythroleukaemia with signs of a haemolytic component (reticulocytosis, hyperbilirubinaemia, increased osmotic fragility before and after incubation at 37° C for 24 h). Coombs test and tests for complete antibodies were negative. Haemoglobin analysis with starch gel electrophoresis with borate buffer, pH 8.6, and alkali denaturation<sup>1,5</sup> gave normal results, namely foetal haemoglobin less than 1 per cent and no alteration in the content of the normal minor haemoglobin component, haemoglobin  $A_2$  (3.5 per cent). The patient was successfully treated with corticosteroids, and clinical manifestations and haematological findings improved moderately. Nearly 1 year later, a second analysis of haemoglobin was carried out. Repeated determinations of haemoglobin  $A_2$  with different methods such as starch gel electrophoresis<sup>6</sup>, starch block electrophoresis<sup>6</sup> and DEAE-cellulose chromatography<sup>7</sup> showed a very low content, namely between 0.29 per cent and 0.5 per cent (Fig. 1). This finding was confirmed by Dr. C. Pik of the Department of Pediatrics, State University of Groningen, and also at the Central Laboratory of the

Netherlands Red Cross, Amsterdam. In the latter case the following determinations were also performed: serum haptoglobin high normal, glucose 6-phosphate dehydrogenase 64 u/g (normal range  $15.4 \pm 6.7$  u); glutathione reductase 48 u/g (normal range  $15.4 \pm 4.4$  u); pyruvate kinase 27.9 u/g (normal range  $41.7 \pm 10.6$  u). The concentration of serum iron was between 220 and 240  $\gamma$  per cent on repeated determinations during the course of his illness. The patient died 1.5 years after the onset of leukaemia.

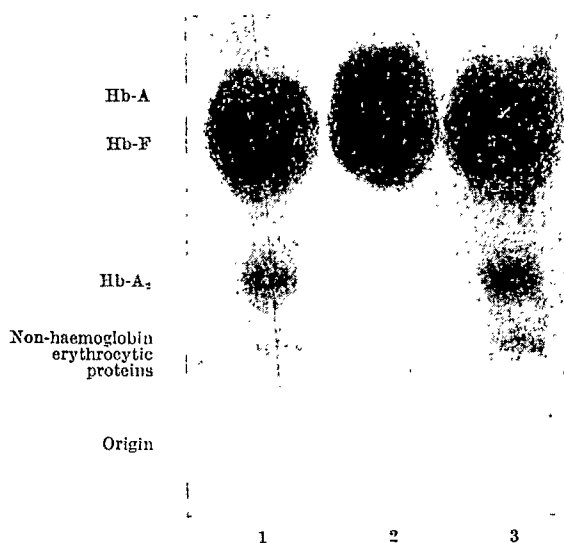

Fig. 1. Starch gel electrophoresis with borate buffer, pH 8.6. 1, Patient with Cooley's anaemia: Hb-A + Hb-F + Hb-A<sub>2</sub> (increased concentration); 2, propositus: Hb-A(Hb-A<sub>2</sub> is not visible due to its extremely low concentration); 3, normal: Hb-A + Hb-A<sub>2</sub> (normal concentration). The gel was photographed after staining with buffalo-black in methanol.

A decrease of the haemoglobin A<sub>2</sub> fraction in adults has been observed in the following states: (a) in some forms of thalassaemias, such as  $\alpha$ -thalassaemia (haemoglobin H) or in certain cases of F-thalassaemia<sup>8,9</sup>; (b) when variants of haemoglobin A<sub>2</sub> such as haemoglobin A<sub>2</sub>' or haemoglobin Flatbush are present<sup>10,11</sup>; (c) in the presence of haemoglobin Lepore in the heterozygous state<sup>12</sup>; (d) in some cases of severe and long standing iron deficiency anaemia<sup>13</sup>. (Some other conditions in which haemoglobin A<sub>2</sub> is completely absent are not included in this discussion.)

The results of analysis of haemoglobin and the presence of high values for serum iron easily excluded all the possibilities mentioned above. Another important fact in the evaluation of the decrease of haemoglobin A<sub>2</sub> in our erythroleukaemic patient is its occurrence in the course of his illness. At the beginning the percentage of haemoglobin A<sub>2</sub> was found within normal limits, that is 3.5 per cent, by the method of starch gel electrophoresis. Contrary to this, one year later the haemoglobin A<sub>2</sub> fraction decreased to a content of 0.29–0.5 per cent as measured by the method of starch block electrophoresis and DEAE-cellulose chromatography. This shows clearly that the decrease of haemoglobin A<sub>2</sub> developed during the course of erythroleukaemia. In other words, the decrease of haemoglobin A<sub>2</sub> fraction may be considered an acquired phenomenon.

A possible explanation of the decrease of the haemoglobin A<sub>2</sub> fraction in a leukaemic patient is that the leukaemic state sometimes leads to an imbalance of haemoglobin chain synthesis which results in a relative excess of  $\beta$ -chains or a compensatory production of  $\gamma$ -chains<sup>4</sup>. In our case, this imbalance led to a decrease in the production of  $\delta$ -chains resulting in a low concentration of haemoglobin A<sub>2</sub> without compensatory production of  $\beta$ - or  $\gamma$ -chains as shown by the absence of haemoglobin F and H.

### Specificity of Sugar Carriers in Erythrocytes

The mechanism of exchange transport can be explained in various ways<sup>1,2</sup>, but it is evident that substances participating in it penetrate through the membrane using the same carriers. This type of transport can therefore be used to investigate substances which share common carriers. The specificity of sugar carriers in erythrocytes was investigated by this method and the results indicated that only some of the monosaccharides share the same carriers<sup>3</sup>. The others pertained to monosaccharides which had a lower affinity for the carriers<sup>4</sup>. The objection has been made that in experiments with sugars of low affinity to the carrier it was only their low relative concentration in the medium (that is, concentration with regard to the affinity) that could be the reason for the lack of exchange transport<sup>5</sup>. We have explored this suggestion and followed the exchange transport of glucose for L- and D-arabinose (that is, sugars with a quite different affinity for the carrier<sup>4</sup>) at the same relative concentrations.

Blood was collected in ACD solution (35 g of glucose, 11 g of trisodium citrate, 4 g of citric acid in 1,000 ml. of water). After separation of erythrocytes from plasma, 0.5 ml. of erythrocytes (containing 5.7 mg of glucose/ml.) was incubated in a solution of D-arabinose (260.6 mg/5 ml. of water), L-arabinose (20.85 mg/5 ml. of 0.9 per cent sodium chloride), and in 0.9 per cent sodium chloride. After 1, 7 and 13 min of incubation at 0° C samples of the suspension were withdrawn and erythrocytes were separated by filtration through a 'Hyflo Super Cel' layer<sup>6</sup>. After haemolysis, the proteins were precipitated and glucose determined from the difference in reduction power before and after oxidation with glucose oxidase<sup>7</sup> and chromatographically<sup>8</sup>.

In order to obtain the same values for relative concentration (with regard to the affinity for the carrier) of L- and D-arabinose the dissociation constants of these two sugars were assessed from the figure in the paper of LeFevre and Marshall<sup>4</sup> ( $K_s$  for L-arabinose 0.12 mole/l.,  $K_s$  for D-arabinose 1.5 mole/l.). The affinity of L-arabinose to the carrier is about 12.5 times higher than that of D-arabinose, and so we dissolved 12.5 times more D-arabinose than L-arabinose. To maintain approximately isotonic conditions, L-arabinose was dissolved in 0.9 per cent sodium chloride, and D-arabinose in distilled water.

Fig. 1 shows that the efflux of glucose into the L-arabinose medium was significantly higher than that into

the D-arabinose medium; in the latter case the efflux was similar to that into 0.9 per cent sodium chloride (see also chromatogram in Fig. 2). Fig. 3 shows that during the incubation in L-arabinose the intensity of glucose spots (corresponding to the amount of glucose in erythrocytes) decreases while that of L-arabinose spots gradually increases. In incubation of erythrocytes in the medium with D-arabinose this sugar rapidly penetrates into cells under our conditions (Fig. 3); efflux of glucose is only slight.

These results suggest that L-arabinose (that is, the sugar sharing the common carrier<sup>3</sup>), unlike D-arabinose (the sugar reported not to share the common carrier<sup>3</sup>), accelerates the efflux of glucose even in conditions where the relative concentrations of both sugars with regard to their dissociation constants are the same. It should be noted that as a measure of the affinity we used the dissociation constants estimated at 37° C (ref. 4) while the experiments were carried out at 0° C. A similar relation must therefore be assumed for the temperature changes of the

Fig. 1. Efflux of glucose into media with L-arabinose, D-arabinose, and 0.9 per cent sodium chloride. Erythrocytes (0.5 ml. containing 5.7 mg of glucose/ml.) were incubated in the following media: ○, 20.85 mg of L-arabinose/5 ml. of 0.9 per cent sodium chloride; ●, 250.6 mg of D-arabinose/5 ml. of water; □, 0.9 per cent sodium chloride. ×, Concentration of glucose at beginning of experiment. After 1, 7 and 13 min, the samples were withdrawn and glucose was determined (for details see text).

Fig. 2. Chromatogram showing the efflux of glucose in D-arabinose or into 0.9 per cent sodium chloride. 1-3, Erythrocytes were incubated in D-arabinose; 4-6, erythrocytes were incubated in 0.9 per cent sodium chloride. Analyses for the contents of sugar in erythrocytes were carried out after 1, 7 and 13 min of incubation. Upper row, D-arabinose; lower row, glucose. The conditions of the experiments are given in Fig. 1.

Fig. 3. Chromatogram showing the efflux of glucose into D-arabinose or L-arabinose. 1-4, Incubation of erythrocytes in D-arabinose; 5-8, incubation in L-arabinose. Analyses were carried out after 1, 7, 13 and 20 min. Upper row, arabinose; lower row, glucose. The conditions of the experiment are given in Fig. 1.

dissociation constants of L- and D-arabinose. There is no doubt, however, that although the concentration of D-arabinose was one order of magnitude higher than that previously used<sup>3</sup>, again no significant difference was found between the penetration of glucose into the media with D-arabinose and that into 0.9 per cent sodium chloride without sugars.

It is of further interest that, although D-arabinose under these conditions appeared in erythrocytes within the first minute of the incubation, the efflux of glucose was not accelerated. Provided that it is not merely a question of adsorption of D-arabinose on the membrane, this finding also indicates differences in the uptake of glucose and L-arabinose on the one hand, and of D-arabinose on the other.

I thank Professor P. G. LeFevre for helpful comments.

## BIOLOGY

### Estimation of Survey Efficiency for Animal Populations with Unidentifiable Individuals

IN any census of an animal population a number of individuals may remain undiscovered and this makes the estimation of population size difficult. Various statistical procedures may be used to overcome this problem<sup>1,2</sup>, but these methods usually require the identification of the individuals: that is, that animals revealed during one count should be recognized during other counts. To our knowledge there is published only one method<sup>3</sup> for estimation of the efficiency of a survey and the size of populations containing unidentified individuals, but the validity of this method has been questioned<sup>4</sup>.

We present here a brief description of two techniques for estimating the efficiency of a survey from repeated

counts of a population which do not require identifiable individual members.

In the first method, which we will call the variability method, variability in the results of repeated counts of a population is used to obtain an estimate of the efficiency of survey. We suppose that a population of constant size of  $N$  individuals is counted  $n$  times. In count  $i$  ( $i=1, 2 \dots n$ )  $X_i$  individuals are discovered. The estimator

$$\hat{p}_v = 1 - \frac{S^2}{\bar{X}}$$

can be shown to give a useful estimate of the efficiency of the survey where  $\bar{X}$  is the sample mean of the number of individuals discovered during the counts

$$\bar{X} = \frac{1}{n} \sum_i X_i$$

and

$$S^2 = \frac{1}{n-1} \sum_i (X_i - \bar{X})^2$$

We suppose the  $X_i$ 's to be independently and binomially distributed  $b_N(x, p)$ .  $E(X) = Np$  and  $E(S^2) = Np(1-p)$  and so  $\hat{p}_v$  can be used to estimate  $p$ . Approximation formulae for the expectation and variance for  $\hat{p}_v$  have been computed

$$E(\hat{p}_v) = p - \frac{1-p}{nN} \quad (1)$$

$$V(\hat{p}_v) = \frac{2(1-p)^2}{n-1} + \frac{5p-3p^2-2}{nN} \quad (2)$$

The bias and variance are estimated by substituting  $\hat{p}_v$  for  $p$  and  $\frac{\bar{X}}{N}$  for  $Np$  in (1) and (2). The bias may become noticeable in very small populations and then a corrected estimate may be obtained from (1).

The variance is only moderately dependent on the size ( $N$ ) of the population. This means that the usefulness of the method is very much increased if it is possible to subdivide the population into smaller populations (for example, in area taxation, to subdivide the area) in such a way that one can assume the size of the sub-populations to be constant. Suppose the number of sub-populations to be  $K$ . It is then possible to obtain counts and estimates  $\hat{p}_v^j$ ,  $j=(1, 2 \dots k)$  from each sub-population, and to obtain an average estimate

$$\hat{p}_v = \frac{1}{k} \sum_{j=1}^k \hat{p}_v^j$$

If the original population is subdivided into  $k$  sub-populations the variance of the efficiency estimate will be reduced by a factor of nearly  $1/k$  compared with the variance of an estimate calculated on the basis of an undivided population.

The second method, which can be called the varied observation period method, uses differences in the results of high and low speed surveys of strips or areas to give an estimate of survey efficiency. In the high speed survey each individual will be under observation for a shorter time than in the low speed survey, which causes differences in the number of discovered individuals.

One specific condition must be met: two sightings of the animal in any two distinct time intervals during the period of observation must be independent. In these conditions the probability  $P(t)$  of discovering an individual in an observation period of length  $t$  will be

$$P(t) = 1 - \exp(-\lambda t)$$

where  $\lambda$  is a certain constant.

If a survey of a strip or area with a given speed  $v$  and with efficiency  $p$  is undertaken, and the survey of the same strip or area is carried out  $n$  times,  $n \geq 1$ , then the average number  $X$  of animals discovered depends on the constant population size  $N$  and  $p$ . We have  $E(x) = Np$ . Suppose then that in one survey we use a lower speed  $v/a$ , where  $a > 1$ . We will find that the efficiency with this speed will be a specific function  $p_a(p)$  of  $a$  and the higher speed survey efficiency  $p$ , provided that the above mentioned condition is met. If  $Y$  is the number discovered in this low speed survey, then  $E(y) = Np_a(p)$ , and it is possible to obtain an estimate  $\hat{p}$  of  $p$  by solving for  $\hat{p}$  in the equation

$$\frac{Y}{\bar{X}} = \frac{p_a(\hat{p})}{\hat{p}}$$

The exact form of the function  $p_a(p)$  will depend on assumptions about the shape of the area the surveyor has under observation at any one time. We shall consider two alternatives. (a) The field of observation is rectangular. (b) The field is circular, and the animals are randomly or evenly spaced. We have computed approximate expressions for the expectation and variance of  $\hat{p}$

$$E(\hat{p}) = p + \frac{p_a(1-p)}{GnN} + \frac{1}{pG} \left( G - \frac{p^2}{2} \cdot \frac{d^2}{dp^2}(p_a) \right) \cdot V(\hat{p})$$

$$G = p \frac{d}{dp}(p_a) - p_a$$

$$V(\hat{p}) = \left( \frac{p \cdot p_a}{G} \right)^2 \cdot \frac{1}{N} \cdot \left( \frac{1-p_a}{p_a} + \frac{1-p}{np} \right)$$

$\hat{p}$  is approximately unbiased. It will often pay to choose  $n > 1$ . The function  $p_a$  has the following forms in the two cases: (a)  $p_a = 1 - (1-p)^a$ ; (b)  $p_a$  is in this case implicitly defined by

$$p = 1 - J(u)$$

where

$$J(u) = \int_0^1 \exp[-u(1-r^2)^{\frac{1}{2}}] dr \quad p_a = 1 - J(au)$$

In (b) a suitable approximation must be made in the calculation.

For smaller values of  $p$  it can be seen that (a) and (b) give approximately the same results, and thus that any specific assumptions about the form of the area of observation are relatively unimportant.

So far the population in the strip or area has been assumed to be constant. An important property of the estimator here described is that it is approximately unbiased even if the population fluctuates.

Possibly this method can also be used in other animal census techniques, so long as the observation period during which an animal can be discovered can be varied, as it is in our example, without changing other relevant aspects of the procedure.

### Leaf Resistance in Succulent Plants

REPORTS in the literature indicate or suggest that the stomata of succulent plants open in the dark and close in the light. This conclusion is based on direct observations<sup>1</sup>, measurements of diffusion with a porometer<sup>2</sup>, and inference<sup>3</sup>. Nishida<sup>2</sup> reported nocturnal stomatal opening in several succulent species, but diurnal opening in others. Thick leaves, few stomata, and small stomatal openings make measurements of the stomatal aperture and subsequent determinations of leaf resistance difficult. The innovation of a resistance hygrometer by Wallihan<sup>4</sup> and van Bavel *et al.*<sup>5</sup> allowed the precise determination of leaf resistance to water vapour transfer in succulent plants without the complications frequently encountered with other methods. Measurements of leaf resistance are based on changes in the resistance of a lithium chloride relative humidity sensor as water vapour diffuses from the leaf to the sensor. The sensor is calibrated with standard length tubes placed over a free water surface; thus the leaf resistance can be estimated in meaningful physical units (sec/cm)<sup>6</sup>. In this communication, we present data indicating the magnitude of leaf resistance to water vapour transfer in *Kalanchoe blossfeldiana* v. Poelln. in the light and dark. *K. blossfeldiana* was chosen because many investigators have used it as an experimental plant for dark carbon dioxide fixation studies<sup>6,7</sup>.

Measurements were made in an environmental control chamber fitted with a glove-box through which the resistance meter could be manipulated. Radiant energy in the chamber was  $5 \times 10^4$  erg/cm<sup>2</sup>/sec at plant height. The plants were kept on 8 h photoperiods. Relative humidity was maintained at  $50 \pm 10$  per cent mean differential and temperature at  $\pm 0.55^\circ$  C. All measurements, except as indicated, were taken on the lower surface of young leaves.

On a thermoperiodic regime of  $26^\circ$  C during the light period and  $21^\circ$  C during the dark, leaf resistance to water vapour transfer was uniformly low in the light and high in the dark (Fig. 1). Several hundred measurements substantiated this conclusion. When the dark period temperature was lowered to  $15^\circ$ , resulting in a diurnal fluctuation of  $11^\circ$ , resistances were somewhat higher in

Fig. 1. Leaf resistance ( $R_L$ ) at the end of a light period of 8 h and beginning of dark period of 16 h on three thermoperiodic regimes. Points are means of six determinations from different plants. ●, Light temperature =  $26^\circ$  C, dark temperature =  $21^\circ$  C; ○, light temperature =  $26^\circ$  C, dark temperature =  $15^\circ$  C; △, light temperature =  $26^\circ$  C, dark temperature =  $26^\circ$  C.

the light and lower in the dark. An apparent night stomatal opening relative to the  $26^\circ$ – $21^\circ$  regime was therefore observed. Indications of night opening, however, were only apparent as the minimum resistances of 5–10 sec/cm measured in the light (on the  $26^\circ$ – $21^\circ$  regime) were not observed in the dark. With no diurnal fluctuation, that is, with day and night temperatures of  $26^\circ$ , the resistances were high in both dark and light. The peak resistances measured immediately after the light period were consistent and reproducible.

The mean steady resistance in the dark (that is, the points between 13 and 16 h of Fig. 1) at  $15^\circ$  was  $26.14 \pm 2.6$  sec/cm while at  $21^\circ$  and  $26^\circ$  they were  $56.7 \pm 8.1$  and  $53.1 \pm 7.2$  sec/cm respectively. The  $15^\circ$  mean resistance was significantly different from the  $21^\circ$  and  $26^\circ$  mean resistances at the 1 per cent level. It is interesting to note that the lower night resistance at  $15^\circ$  can be correlated with the reported accumulation of organic acids at low temperatures<sup>8</sup>.

Nishida<sup>2</sup> observed nocturnal stomatal opening in *K. blossfeldiana*; yet Schwabe<sup>9</sup> did not report nocturnal opening. The experimental temperature conditions of the former worker were, however, quite similar to our  $26^\circ$ – $15^\circ$  regime. Our data, therefore, agree partly with both reports.

Young leaves had significantly lower leaf resistances than older leaves (Table 1), and upper surfaces had generally lower resistances than lower surfaces (Table 2). We estimated the number of stomata on the upper and lower surfaces to be  $3,274 \pm 108$  stomata/cm<sup>2</sup> and  $4,698 \pm 118$  stomata/cm<sup>2</sup> respectively. These differences were significant at the 1 per cent confidence level. Further, we estimated the aperture of open stomata (young leaves) to be about  $2.5\mu$ . The relatively high resistances observed were accountable, therefore, by few and small stomata<sup>9</sup>. Lower resistances associated with the upper surface, however, were not correlated with stomatal density. A striking feature of these data was the greater resistances measured when compared with leaf resistances of non-succulent plants<sup>10</sup>.

Table 1. COMPARISON OF YOUNG AND OLD LEAVES ON A SINGLE PLANT

Age	Leaf pair, from top	$R_L$ sec/cm
Young	3	$12.3 \pm 0.6$
Medium	5	$15.0 \pm 2.5$
Older	7	$99.1 \pm 8.8$

Means are based on three determinations taken during the middle of the light period from the lower surface. Light =  $5 \times 10^4$  ergs/cm<sup>2</sup>/sec, light temperature =  $26^\circ$  C, dark temperature =  $21^\circ$  C, relative humidity = 50 per cent.

Table 2. COMPARISON OF UPPER AND LOWER LEAF SURFACES ON MEDIUM AGED LEAVES OF A FLOWERING PLANT

Surface	Light	$R_L$ sec/cm
Upper	+	$20.5 \pm 6.7$
Lower	+	$53.5 \pm 7.5$
Upper	–	$51.0 \pm 5.4$
Lower	–	$80.6 \pm 5.1$

Means are based on three determinations. Dark measurements were taken by interrupting the middle of the light cycle. Light =  $2.3 \times 10^4$  ergs/cm<sup>2</sup>/sec, light temperature =  $30^\circ$  C, dark temperature =  $19^\circ$  C, relative humidity = 50 per cent.

Transpiration ( $T$ ) and diffusion through the stomata can adequately be described by an equation of the form.

$$T = \frac{D \Delta e}{R_L + R_A}$$

where  $D$  = diffusion coefficient,  $\Delta e$  = gas concentration difference, and  $R_L$  and  $R_A$  = the leaf and air resistances respectively<sup>9</sup>. Under our experimental conditions we estimated  $R_A$  to be 0.5 sec/cm.  $R_A$  is therefore relatively insignificant when compared with the observed values of  $R_L$ , and transpiration in *Kalanchoe blossfeldiana* could be described by an equation of the form

$$T = \frac{D \Delta e}{R_L}$$

Transpiration (and possibly assimilation of carbon dioxide) should vary inversely with leaf resistance. Assuming that leaf resistance ( $R_L$ ) reflects stomatal micro-anatomy<sup>9,10</sup>, changes in resistance will indicate changes in stomatal aperture. These data suggest that in *Kalanchoe blossfeldiana*, unlike many plants, gas exchange is under direct stomatal control<sup>9</sup>.

*Kalanchoe blossfeldiana*, under the conditions of our experiments, did not show significant nocturnal stomatal opening as estimated from leaf resistance measurements. The minimum resistances (of 5 to 10 sec/cm) were measured in the light. Apparent nocturnal stomatal opening was observed on a thermoperiodic regime of 26° C in the light and 15° C in the dark; when compared with 26°–26° and 26°–21° regimes, the lower nocturnal leaf resistances were statistically significant. In general, leaf resistances were higher than those reported for many non-succulent plants.

### Simple Device for obtaining Synchronous Cultures of Algae

SYNCHRONOUS cultures (populations of algae in which cell divisions and interphase preparations for division are phased or synchronized) are often used in studies of the algal life-cycle. The devices and methods used to obtain synchronous cultures of algae are as a rule rather complicated<sup>1-3</sup>, so we developed a device of simple construction, the parts of which are easy to obtain. To synchronize the cultures we chose the method in which a random culture is subjected to a regular alternation of light and dark periods of adequate duration.

Fig. 1 shows a well stirred thermostat made solely of glass (36 × 23 × 26 cm) in which two culture vessels can be placed. As culture vessels we used flat bottles of capacity 1 l. Each bottle was provided with two air-inlet tubes, one outlet tube and one tube, adjustable at variable depths, to collect samples and to dilute the suspension.

The cultures were illuminated by four fluorescent lamps through each of the two longest sides of the water bath, giving a light intensity, measured in the middle of the water bath, of 15,000 lux from each side.

To get more light and a spectrum that resembles more closely that of the Sun a high pressure mercury fluorescent lamp should be placed over each culture. This gives from above a light intensity of 5,000 lux in the centre of the thermostat. Placing three thermostats between the lamps enabled us to use three different temperatures and also culture six different organisms at the same time under the same light conditions, to yield about 900 ml. of a dense suspension from each bottle.

With this device we obtained completely synchronized cultures of *Scenedesmus obliquus*, *Ankistrodesmus falcatus* and *Chlorella vulgaris* at temperatures between 25° C and 30° C, using the culture solution of Lorenzen<sup>1</sup>. The light-dark rhythm was 14 h light : 10 h dark, and aeration was achieved with sterile air enriched with 3 volume per cent carbon dioxide. To start cultures we inoculated a small quantity (about 2 ml.) of cells from a liquid stock culture (about  $2 \times 10^8$  cells/l.) into the bottles containing 900 ml. of sterile culture medium. After three light-dark cycles the algal suspensions were dense enough to be diluted for the first time. The stock cultures were grown in slightly modified Rodhe's culture solution 8 (ref. 4). When culture vessels and culture solutions were sterilized (20 min at 120° C) no serious infections occurred during sampling and dilution. Fig. 2 shows the change of cell numbers and relative chlorophyll quantities during one light-dark cycle of *Scenedesmus obliquus*.

Table 1 gives the number of cells and the relative chlorophyll quantities in six succeeding periods of the light-dark change of this organism.

As the average number of autospores of *Scenedesmus obliquus* in these cultures appeared to be ten, we diluted

tenfold with fresh, sterile culture medium at the end of each dark period.

These results are obtained by means of the extra light from the high pressure mercury fluorescent lamps ('Philips HPL 80 W'). Without these lamps and thus with the light of the fluorescent lamps ('Philips TLF 65 W 33') only, complete synchronization occurred as well, but the average autospore number was slightly lower and the chlorophyll synthesis in the dark was lower. Also we observed a temporary decrease of the amount of chlorophyll at the start of sporulation, the meaning of which is not yet clearly understood.

### Disappearance of Bacteria from the Zone of Active Mycorrhizas in *Tricholoma matsutake* (S. Ito et Imai) Singer

IN coniferous forests in Japan, especially forests which contain *Pinus densiflora*, the edible mushroom "matsutake" (*T. matsutake*) forms fairy rings of fruiting bodies on the ground. The ring follows the mycorrhizal development of pine rootlets and grows outwards 10–15 cm every year. On the inner area of the fairy ring where the mycorrhizas have been decomposed, fruit bodies are seldom formed<sup>1,2</sup>.

Previous studies on the microflora of soils<sup>3</sup> gave little information on the interactions between mycorrhizal fungi and soil bacteria. In this communication some characteristics of bacterial population in the zone of active mycorrhizas of *T. matsutake* and the vicinity\* will be reported; the interactions between pine roots and the mycelia are described in another paper<sup>2</sup>.

A soil profile about 50 cm deep and about 100 cm wide was prepared by trenching along the line through the centre of the fairy ring and through the point IV (0,0) (see Fig. 1), where the fruiting bodies of the matsutake mushrooms occurred in 1964.

Soil samples were obtained by inserting sterilized glass tubes into the soil at various points on the profile shown in Fig. 1. This method avoided contamination from organic matter on the soil surface.

\* This area is called "Shiro" in Japanese, which means "a castle" and may be accepted as a subterranean biotic community where the mycorrhizal development plays a leading part over the soil constituents, especially soil microbes<sup>4</sup>.

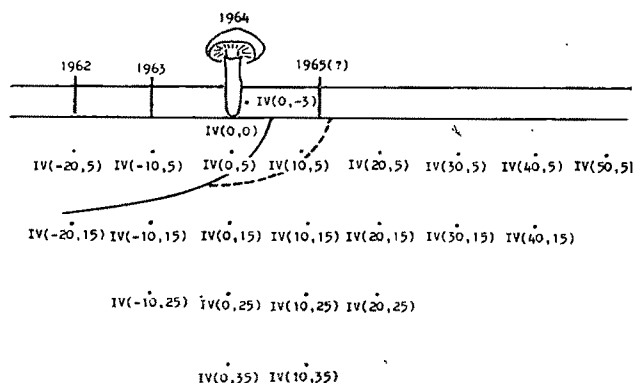

Fig. 1. Soil profile of "Shiro" in June 1965. IV (0,0) is the site of fruiting bodies in October 1964. In a sampling point designated as IV ( $x, y$ ),  $x$  indicates the distance (cm) and  $y$  the depth (cm) from IV (0,0). The solid curve illustrates visible border of white mycelial layer in October 1964, and broken one that in June 1965. The area enclosed by these two curves contains active mycorrhizas.

Since November 1964, soil has been sampled about once a month at Iwakura, Kyoto, in a forest consisting of 70–80 year old *P. densiflora*.

Isolation and estimation of bacteria were made mainly by the dilution plate method using the following media: GPYS agar†; soil extract agar<sup>4</sup>; Thornton's asparagine-mannitol agar<sup>4</sup>; nitrogen free mannitol solution<sup>4</sup>; thio-glycolate semi-solid nutrient agar<sup>4</sup>; beef extract peptone agar. Direct smearing of sampled soils on GPYS and soil extract agar slant was also done. All the isolation procedures were done within 12 h of sampling and the cultures were incubated at 30° C for 72 h. For mycelium of *T. matsutake*, 30° C is lethally high, and 72 h is not a sufficient time for it to grow<sup>7</sup>.

Neither bacteria nor actinomycetes were isolated from the point IV (0,5), right above which the fructification of matsutake occurred in October 1964; on the nutrient plates, only colonies of *Mortierella* spp. (Phycomycetes) that were commonly obtained from almost all samples were observed.

From the soil samples outside the active mycorrhizal zone [sampling points IV (10,5), (20,5), etc.; IV (0,–3) = humus layer and IV (0,15)], bacteria and actinomycetes were obtained abundantly, especially from the soil samples at IV (40,5) and (50,5) (Fig. 2b). Among them, *Pseudomonas* spp., *Arthrobacter* spp., *Agrobacterium* spp. and others were found.

From the soil through which the front of the active mycorrhizal zone had passed [IV (–10,5) and (–20,5)], bacteria and actinomycetes were seldom isolated, and remarkable aggregation and desiccation of the soil were observed. But in the soil near the centre of the ring, some bacteria and actinomycetes began to appear. The pH value of the soil of active mycorrhizas (4.6–4.7) was higher than that outside (4.1–4.4), but the water content of the former (11.0–12.0 per cent) was lower than that of the latter (15.0–19.0 per cent) (Sagara, N., unpublished data).

A seasonal change of bacterial population is another characteristic of the "Shiro". When sampled in the spring and early summer of 1965, bacteria and actinomycetes were observed to disappear from the point IV (10,5), where many of them were isolated in the autumn of 1964 (Fig. 2, left). During this period, the front of the active mycorrhizal zone advanced about 10 cm.

Similar results were obtained from the "Shiro" soils sampled at another place in Kyoto, at a place in Okayama Pref., at three places in the north-east of Japan (two of them near the northern limit of *Pinus densiflora* and one on a coastal sand dune) and at two places on the northern

† GPYS agar contains 10 g glucose; 10 g peptone; 5 g yeast extract; 100 ml. soil extract; 15 g agar and 900 ml. tap water; pH 6.8 and 5.0 (GPYS-1 and 2 respectively).

Fig. 2. *a*, Colonies isolated in June 1965 from IV (10,5) on GPYS-1 agar plate after incubation for 48 h at 30° C. Bacteria and actinomycetes are completely eliminated and only colonies of *Mortierella* spp. are observed. The same results were obtained from IV (0,5) in November 1964. ( $\times$  c. 0.6.) *b*, Colonies isolated in June 1965 from IV (40,5) on GPYS-1 agar plate after incubation for 48 h at 30° C. Bacteria, actinomycetes and *Mortierella* spp. are observed. ( $\times$  c. 0.6.)

slope of Mount Fuji (one of them in *Abies veitchii*—*Tsuga diversifolia* forest).

The fine rootlets of pine developing in the active mycorrhizal zone branch like witches' brooms<sup>2</sup>. Because the sample from the point IV (10,5) was obtained from the soil containing rootlets with these characteristics, and *Mortierella* spp., which were isolated from the soil sample, had no inhibitory effect on the growth of bacteria *in vitro*, the disappearance of bacteria, especially aerobic and heterotrophic ones as well as actinomycetes, might be closely related to the mycelial activity of *T. matsutake* or to the mycorrhizal development of pine rootlets.

### Rate of Glucose Oxidation in Sea Urchin Eggs

ACCORDING to Bullough<sup>1</sup>, the principal process providing energy for mitosis is the oxidation of glucose during the period before prophase (antephase or preprophase). His views are not generally accepted<sup>2</sup> and cannot be extended to all instances of cell division<sup>3</sup>. On the other hand, they appear to hold for cleaving sea urchin eggs and for those of some other animals as the respiration rate of eggs increases during the period before mitosis<sup>4,5</sup>. Unfortunately, these results have not been substantiated by other authors<sup>6</sup> so that the question of the respiration cycle during egg cleavage remains open.

In order to check Bullough's concepts and the data obtained by Zeuthen<sup>4,5</sup> we have investigated the rate of glucose oxidation at different stages of the three first cleavage divisions in the eggs of *Strongylocentrotus dröbachiensis* (O. F. Müller). The work was carried out in the Murmansk Marine Biological Institute. 8,000–12,000 sea urchin eggs were placed in Warburg flasks in 4 ml. of a solution of <sup>14</sup>C glucose in sea water. The rate of oxidation of <sup>14</sup>C glucose was measured from the radio-

activity of the carbon dioxide produced with 10 per cent potassium hydroxide solution. The temperature during the experiments ranged from 6° to 7° C.

In the first experiment the eggs were placed into <sup>14</sup>C glucose solution for 40 min, at different times after fertilization, and Warburg flasks were stoppered. After 60 min more, potassium hydroxide samples (0.2 ml.) were taken to determine labelled carbon dioxide. In all, four experimental series were carried out on the eggs taken from four females. Fig. 1 summarizes the results obtained in these experiments. It can be seen that the rate of oxidation of <sup>14</sup>C glucose rises considerably during the period between divisions, and decreases during mitoses.

To find whether or not this change in the rate of oxidation of <sup>14</sup>C glucose during divisions is related to rhythmic changes in the permeability of the egg to glucose, a second experiment was carried out. Sea urchin eggs were placed into <sup>14</sup>C glucose solution 30 min after fertilization and kept there for 6 h up to the stage of eight blastomeres. Potassium hydroxide samples for radioactivity measurements were taken every 40 min, the reagent being completely replaced each time by freshly prepared solution. The results of this experiment are shown in Fig. 2. They do not differ considerably from those of the first experiment (Fig. 1): the rate of oxidation of <sup>14</sup>C glucose increased in the period between divisions and decreased during mitoses. It should be emphasized that the data obtained in the second experiments are more clearly expressed. It is particularly interesting that in this experiment the maximal increase in the rate of oxidation of <sup>14</sup>C glucose is found in the phase before prophase, thus adding weight to the hypothesis of the presence of a special phase (antephase) in cell division. A considerable rise in the rate of oxidation of <sup>14</sup>C glucose at the third division of sea urchin eggs compared with that at the first and second divisions seems to be associated with a gradual increase in the concentration of carbon-14 in the eggs.

Thus the results obtained on the rate of oxidation of <sup>14</sup>C glucose at different stages of the first three divisions in eggs of *Strongylocentrotus dröbachiensis* support the findings of Zeuthen that the respiration rate of sea urchin eggs increases in the period between mitoses, as well as Bullough's concept of the part played by glucose oxidation in providing energy for mitoses. These observations do

Fig. 1. Rate of oxidation of <sup>14</sup>C glucose (measured from the radioactivity of carbon dioxide) at different stages of the first three cleavage divisions of sea urchin eggs. P, Prophase; M, metaphase; A, anaphase; T, telophase.

Fig. 2. Rate of oxidation of <sup>14</sup>C glucose at different stages when sea urchin eggs are kept continuously in <sup>14</sup>C glucose solutions during the first three cleavage divisions.

not contradict the hypothesis advanced by Swann<sup>7</sup> that there is an energy reservoir that fills before mitosis. On the basis of our results it can be assumed that the filling of the energy reservoir in sea urchin eggs proceeds at the expense of glucose oxidation. Finally, it seems that an increase in the rate of oxidation of glucose in the period between divisions of sea urchin eggs is related to an activation of the enzymes of the hexose monophosphate shunt, as it is known that glucose oxidation at cleavage is realized mainly by way of the hexose monophosphate shunt<sup>8</sup>. This confirms the observations that in synchronized fibroblast cultures the concentration of glucose-6-phosphate dehydrogenase (which controls the hexose monophosphate shunt) rises in the period between divisions and falls during mitoses<sup>9</sup>.

### Kinetin-treated Flax Seedlings as Models for the Integration of the Plant Body

AMONG the many morphological experiments performed on various seedlings<sup>1</sup> a recent experiment indicated in Fig. 1 seems to be particularly suitable to further the understanding of the growth correlations which are responsible for the integration of the plant body. Seedlings of *Linum usitatissimum* when decapitated above the first leaf pair always replace the lost top, when the cotyledonary buds grow out vigorously and prevent the development of the buds which are above them in the axils of the first two leaves, because the cotyledonary buds exhibit a much more advanced embryonic development because the cotyledons have a larger area than the first leaves. Kinetin immediately applied in 1 per cent lanolin to the bud of the first leaf caused it to expand, as in other cases<sup>2-4</sup>, but the cotyledonary shoots, even in this case, grew out more strongly and finally inhibited the shoot pretreated with kinetin (Fig. 1a).

When, in addition, the root and most of the hypocotyl were removed simultaneously, only the bud treated with kinetin developed when plants were placed simply on a water surface (Fig. 1b). In spite of their initially greater embryonic differentiation the cotyledonary buds remained in this case quite small, apparently because of a lack of particular metabolites of the root. The transport of these latter could be blocked by indolyl-3-acetic acid in 0.5 per cent lanolin, placed in the form of a ring at the upper end of the hypocotyl, under the cotyledonary node. In such plants with the root left the expansion of the previously much larger cotyledonary primordia was suppressed when the first leaf bud was treated with kinetin. These results agree with the well known action of kinetin which causes, for example, accumulation of proteins and nucleic acids, renewed formation of chlorophyll in senescent leaves, and activation of auxin<sup>5-10</sup>. All these effects of kinetin are diminished if the roots are preserved.

The correlative influence of the roots enhances the obvious apical dominance, allowing in intact *Linum* seedlings a very limited expansion of the lateral buds which have been treated with kinetin. The regular dominance of the bud of the first leaf which has been treated with kinetin in decapitated seedlings without the root

Fig. 1. *Linum usitatissimum*, decapitated seedlings, treated with kinetin paste on the bud of the first leaf, marked by (\*). a, Root and hypocotyl were left and the cotyledonary buds developed more strongly and b, these organs were removed and only the bud of the first leaf, which had been treated with kinetin, developed.

and hypocotyl shows that many other such differences in the state of the embryonic development of the buds, their position on the plant and their attachment to the conducting system can be prevented by localized application of kinetin. This does show very clearly, however, the primary importance of root activity in the correlative integration of the plant body.

### Living Root System distinguished by the Use of Carbon-14

THERE is no adequate method to distinguish a functional root from a non-functional or presumably dead root. An electrical technique has been used<sup>1</sup> to diagnose the vitality of portions of roots of some weeds by measuring the resistance and capacitance of the tissue. Vital staining, in many cases with triphenyl tetrazolium chloride, has also been used for seedlings of grasses such as rice<sup>2</sup>. These methods, however, can only be used when the root is thick enough to allow insertion of an electrical probe into tissues or when the root is so young that a stained portion may be easily seen.

Accordingly, there is need of a satisfactory and more widely applicable method, for grasses which are grown in the field, to distinguish functional or non-functional parts of the root system.

We applied carbon-14 to the leaves of seedlings of Italian ryegrass (*Lolium multiflorum* Lam.) and traced the translocation of labelled assimilates to various parts of the root system, to ascertain whether they were readily translocated to non-functional roots, because carbohydrates are metabolites of living cells of the tissue.

Fig. 1. Distribution of carbon-14 in the root system of 3-month-old Italian ryegrass seedlings. (a) The plant material and the part of root which was killed throughout its length is indicated by an arrow; (b) autoradiograph of the same plant.

Seedlings of Italian ryegrass were grown in small pots in glasshouse conditions and, after 3 months, plants were removed and parts or whole lengths of some roots were killed in boiling water before replacement in the pots. Carbon-14 (20  $\mu\text{C.}/\text{plant}$ ), in the form of carbon dioxide, was applied to the plants in the pots, which were placed in a plastic, air-tight, chamber and the plants were fed for 3 h at 22°–25° C in natural light. Plants were then taken out of the pots and washed thoroughly in running water. After sufficient freeze drying to permit autoradiography, each piece of plant material was mounted on a sheet of paper and exposed to X-ray film. After 2 days satisfactory autoradiographs were obtained.

Autoradiographs revealed that labelled assimilates were not readily transferred to the dead parts of the root system. This is more marked in whole root lengths which had been killed as is shown in Fig. 1, in which the dead part of the root system is arrowed (a). The autoradiograph of the same plant (b) shows few images in the dead roots and, in the living parts of the roots, images are distributed evenly throughout the whole length, but images around the root tips develop rather strongly.

This suggests that assimilates cannot readily move down to the non-functional roots; our technique may be applicable to a growing plant on the field.

In the next trial, we have applied this technique to an Italian ryegrass sward to observe its effect on older plants. Italian ryegrass was planted in spaces 20 cm apart in November 1964 on a field of volcanic acid soil. On May 18, 1965, a bottomless plastic chamber large enough to cover four plants simultaneously, 30 cm wide, 50 cm long and 30 cm high, was placed on the sward and the edges of the side wall of the chamber were fixed to the soil surface by a trench, in which was slightly acid water; this made the chamber air-tight. Two cocks of the chamber were connected to a carbon dioxide generator and an air pump by means of rubber tubing, so that the gas circulated through the chamber with a velocity of about 1 l./min.

Carbon-14 (100  $\mu\text{C.}$ ) was applied to each plant for 1 h at 25°–30° C. After feeding, excess labelled carbon dioxide was absorbed by dilute alkali solution, the chamber was removed, and the roots were taken out of the soil with an iron core sampler 10 cm in diameter and 10 cm deep. Blocks of soil were thoroughly washed and the tops were detached just below the crown. All detached roots were killed by placing in boiling water for 1 min, washed, dried and mounted on a sheet of paper after each individual root had been trimmed to a length of 3 cm as shown in Fig. 2. After exposure to X-ray film for 7 days, the autoradiographs were developed.

We counted the number of roots in the sample and the number of these which developed images in the autoradiograph and calculated the ratio of the latter to the former. There was a large range of blackness among the images, but the following results were obtained: the mean number of roots/plant was  $267.5 \pm 58.2$ ; the mean number of roots with images was  $243.5 \pm 46.6$ ; the percentage of roots with images was  $91.7 \pm 3.7$  per cent. This revealed that only 8 per cent of all the roots had lost their function by the middle of May while the rest of the roots were still functional. This large number of functional roots also seemed to

correspond with vigorous vegetative growth of tops which yielded  $15.61 \pm 3.19$  g on a dry weight basis.

There are some problems to be solved with this technique. One of them concerns the rate of translocation of assimilates to underground organs which depends on the age of the individual leaf and tiller of the shoot system<sup>3</sup> as well as on the growth stage of the plant. Flower initiation, in general, seems to retard this downward translocation, for at this stage of reproduction most photosynthetic products tend to move to the ear. This upward translocation is detrimental to our technique, so some treatments, for example removal of flower organs, are necessary before the application of carbon-14.

Another problem concerns the distribution of translocated assimilates within the root tissue. As in the case of the seedling, we observed assimilates distributed evenly throughout the root, but the same distribution also occurs

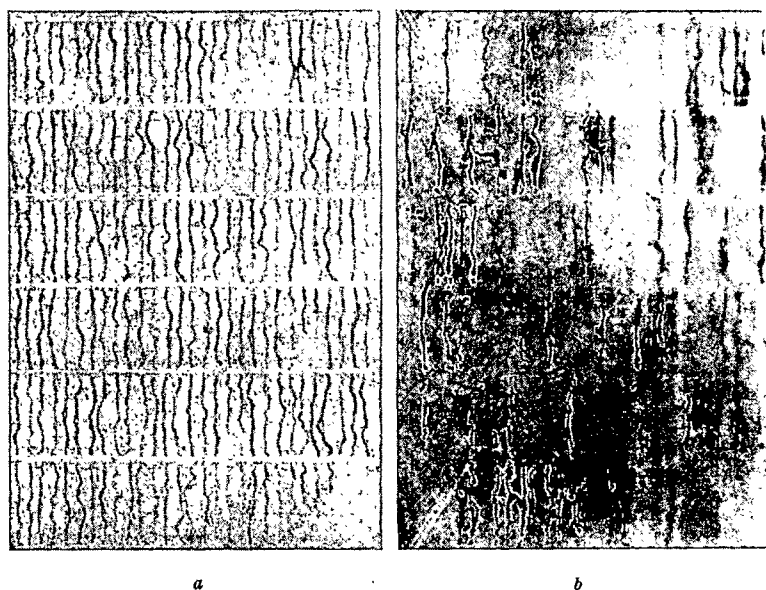

Fig. 2. Distribution of active carbon-14 in the root system of older Italian ryegrass on the field. (a) Roots which were trimmed to 3 cm long; (b) autoradiograph of the same sample.

in an older root. If the distribution in the root tissue is uneven, assimilates can accumulate in the lower part of roots, even if the upper part of the root such as those 3 cm long in this trial shows no image on an autoradiograph. In this case, we suppose that it is better to collect much longer roots.

We believe that this technique provides an approach to the understanding of the function of the roots particularly in perennial herbs.

We thank R. D. Williams of the Grassland Research Institute, Hurley, for advice.

## AGRICULTURE

### Definite Record of *Fomitopsis annosa* in Australia

For many years *Fomitopsis annosa* (Fr.) Karst (= *Fomes annosus*) has been closely investigated in other countries because it is a facultative parasite of plantation grown softwood timbers which kills trees and causes heavy losses from heart rot. In Scandinavia it has been reported to cause losses of forest yield which vary from 30 per cent to 90 per cent, and in south-east Europe it has been described as one of the most devastating diseases in primeval forests of conifers<sup>1</sup>. It appears to be much less important as a parasite in Great Britain and the United States, although it is still an important cause of heart rot, especially in plantations.

Until last year it was believed here that Australia was free from *F. annosa*. Its presence was reported during the last century in both Queensland and New South Wales<sup>2</sup>. The latter collection has been cited but not confirmed in identity from the remains housed at Kew. There was considerable doubt as to the correctness of these identifications, and P. H. B. Talbot (personal communication, 1961) also concluded that no authentic evidence of its occurrence here was available. In June 1964, however, A. W. Gardner of the Queensland Department of Forestry at Atherton, North Queensland, sent me four fruit bodies collected from dead stumps of hoop pine (*Araucaria cunninghamii* Ait.) which I tentatively identified as *F. annosa*.

The general appearance and microstructure of the fruit bodies were very similar to a previous comprehensive description given<sup>3</sup> and also to specimens received in our herbarium as *F. annosa* from England, the United States, Portugal and India. Basidiospores were not seen, but all other characters corresponded closely. Cultures were isolated from some of the fruit bodies and agreed with another description<sup>4</sup> including the presence of the highly characteristic and unusual oedocephaloid conidiophores. P. H. B. Talbot (personal communication, 1965) agrees that the Atherton fungus is identical with *F. annosa*, and both fruit bodies and cultures have also been submitted to American workers for confirmation of these. C. S. Hodges, jun., who is making an intensive investigation of this species, states (personal communication, 1965) that it is morphologically identical with *F. annosa* as it occurs in the United States and elsewhere.

Despite these confirmations it is not certain that this fungus has the same parasitic abilities as, or is even conspecific with, the destructive European forms. From its location it seems to be endemic and its occurrence within the tropics is unusual for *F. annosa*, but reports give no

evidence of parasitic effects. It may be related to the form found in temperate rain forests in New Zealand on the closely related timber *Agathis australis* (kauri) or to the Philippine form<sup>5</sup> as *Trametes insularis* on *Pinus insularis*. The New Zealand form does not appear to be parasitic on exotic pines, but its physiological and taxonomic relationships are now being investigated in the United States. Unfortunately, the extreme rarity of clamp connexions in *F. annosa* precludes the normal tests for conspecificity, but it is hoped that other methods may be used.

This record may not therefore constitute any serious threat to the extensive plantings of exotic softwoods in Australia, but it emphasizes the importance of an intensive search for this fungus in, or around, established plantations, especially in areas where tentative earlier records were obtained, such as "Richmond River, N.S.W."<sup>6</sup>. After careful investigation, only one earlier record has been confirmed, at Mallanganee, N.S.W., 1919, collected by J. B. Cleland on hoop pine.

## PSYCHOLOGY

### Time taken to change the Speed of a Response

CRAIK<sup>1</sup>, in seeking to understand the nature of reaction times, questioned whether they were due to stimuli having to pass through a long chain of synapses between sense organ and effector, or whether some "condensed" time lag due to a decision process occurred in one part of the chain. He argued that if the latter was the case, the process would be subject to serious interference from subsequent stimuli unless protected by a form of switching mechanism or "gate". Subsequent experimental work<sup>2</sup> has indicated that the reaction time to a signal ( $S_2$ ) arriving during the reaction time to a previous signal ( $S_1$ ) is longer than when  $S_2$  arrives well after the reaction to  $S_1$ , and the theory (the "single-channel hypothesis") has been advanced that the arrival of  $S_1$  raises a "gate" which is not lowered until the reaction time to  $S_1$  has ended. Reaction to  $S_2$  is thus delayed by the time elapsing between the arrival of  $S_2$  and the end of the reaction time to  $S_1$ . Clear exceptions have been found only when it has been reasonable to regard subjects as able to group  $S_1$  and  $S_2$  into a single unit and respond to both together. Typically, this occurs only when they are less than about 0.1 sec apart, and not always then.

The present communication describes what appears to be a type of exception not previously reported. Subjects were presented with vertical lines rising 1.5 in. from a baseline on a paper band revolving on a kymograph drum behind a screen in which was a vertical slit 10 mm wide. The lines were spaced so as to appear at irregular intervals of 2-3 sec. One group (A) was told that as soon as a blue line appeared they were to draw a line of the same length in the slit and then return to the baseline, making the whole movement smoothly and without hurrying. After forty-five practice lines they were told that occasionally a red line would appear, in which case they should make the movement as rapidly as possible. A second group (B) made their normal responses to the blue lines as rapidly as possible and their occasional responses to the red lines at leisure. For each group the test series consisted of 140 blue lines interspersed with

72 red lines, eight standing alone and eight following blue lines at each of the intervals 25, 50, 75, 100, 150, 200, 250 and 300 msec. A third group (*C*) were given the same instructions as group *A*, except that when a red line occurred they were to stop their movement and pause before returning to baseline. There were three subjects in each group.

The results relevant to the single-channel hypothesis are set out in Fig. 1. They consist of all cases in which  $S_2$  arrived during the reaction time to  $S_1$  and separate responses were made to both. Cases were excluded in which the response to the red line was wholly substituted for that to the blue—a kind of grouping effect which sometimes occurred when the interval between  $S_1$  and  $S_2$  was less than 100 msec. According to the hypothesis the points for each group should lie on a straight line sloping at  $45^\circ$ . Those for group *B* are in very fair agreement with prediction, and this was so for each of the subjects individually: the rank-order correlations ( $\tau$ ) between the two measures plotted in Fig. 1 were respectively  $+0.47$  ( $P < 0.001$ ),  $+0.38$  ( $P < 0.001$ ) and  $+0.28$  ( $P < 0.02$ ). These correlations are high when it is remembered that they are inevitably reduced by any variation in  $S_2$  arising from sources other than single-channel delays. The results for group *A* show no systematic trend and the correlations for all three subjects were very small:  $-0.02$ ,  $-0.05$  and  $-0.06$ . Two members of group *C* behaved like those in group *B* and produced correlations of  $+0.42$  ( $P < 0.001$ ) and  $+0.32$  ( $P < 0.01$ ): their shorter mean reaction times are understandable in that the decision to stop a response is probably simpler than one to change its speed. The third subject in group *C* behaved like those in group *A* with a correlation of  $+0.07$ .

The results shown in Fig. 1 suggest an important refinement of the single-channel hypothesis. The central processes following  $S_1$  were concerned with the initiation of a phased pattern of muscular action, which had to be modified in response to  $S_2$ . Clearly, the extent of this

modification was very different for groups *A* and *B*. The latter, in order to slow a movement down, would have had to change the pattern of muscular innervation substantially, bringing antagonists into play in order to arrest the rapid motion, and it is therefore understandable that the delays found were similar to those observed in a previous study in which movements had to be reversed<sup>2</sup>. For group *A*, however, the speeding up seems likely to have involved merely an intensification of the pattern already in operation. Group *C* should at first sight all have behaved like group *B*, but it is possible that the subject whose performance was like that of group *A* managed simply to discontinue his movements instead of actively arresting them. If so, it seems reasonable to suggest that the decision process protected by the "gate" is the initiation of a fresh pattern of action. Thus a signal to bring other muscles into play is excluded, while signals conveying instructions merely to increase or reduce the activity of those already in action can get through.

### Social Organization of Rats in a "Social Problem" Situation

In general, animals which are kept together form habits of responding to each other which are mostly regular and predictable. Part of the growing interest in the social behaviour of humans and animals is to discover more about the nature of these patterns of responding and the extent to which they vary between different types of animal, in order to build up some sort of "complete picture". Despite the potential usefulness of social experiments in the laboratory with all kinds of animals, the lower vertebrates show only rudimentary capacities for social organization. It is not then surprising that relatively little work has been done on small mammals such as the rat, because rats do not appear to be especially influenced by each other's behaviour. Where there have been experiments designed to study social behaviour in the rat they have been mainly concerned with dominance and aggression; gregariousness; social facilitation; competition and co-operation. Many of these appear to have been designed specifically to test, in an "all or none" fashion, the existence or non-existence of social psychological concepts assumed to be appropriate to a variety of animals, and in particular to the higher primates including man. Studies of co-operation<sup>1</sup> and "altruism"<sup>2</sup> provide examples of this thinking. The question arises as to how much this sort of experimentation has tended to over-emphasize assumed behavioural similarities between animals, rather than using situations thought to be flexible enough also to demonstrate important behavioural differences. One way of attempting to counterbalance this possible limitation is to use well tried techniques previously free from social psychological considerations, and to employ groups of animals in them instead of individuals. With this consideration in mind we have now completed a series of thirty pilot studies in which the social organization of the rat was investigated. Our work is based on a report of Mowrer<sup>3</sup> in which he described a situation which involves groups of rats in a "social problem"—that is, animals were trained to feed themselves by pressing a lever. When groups of three trained rats were placed in the apparatus together, hierarchies of performance emerged. One animal (of each group) did most of the work, the other two

Fig. 1. Times taken to modify the speed of a response.  $\circ$ — $\circ$ , Group *A* (slow to fast).  $\bullet$ — $\bullet$ , Group *B* (fast to slow).  $\circ$ — $\circ$ — $\circ$ , One subject in group *C* (slow to stop) whose performance resembled that of group *A*.  $\bullet$ — $\bullet$ — $\bullet$ , Two subjects in group *C* whose performances resembled that of group *B*. Each point is the mean reaction time to  $S_2$  for a range of intervals between the arrival of  $S_1$  and the end of the reaction time to  $S_1$ . The ranges (from right to left) in msec were 0–49, 50–99, 100–149, 150–199, 200–249 and 250 and over. The numbers of readings contributing to each point for groups *A* and *B* vary from 7 to 38 (mean 20); those for the single subject in group *C* from 2 to 14 (mean 8.2) and for the two subjects in group *C* from 7 to 21 (mean 13.7).

most of the eating! Additionally, the solution was said to persist indefinitely. Apart from the obvious fascination of this as a situation, the investigation of group situations using instrumental conditioning techniques seemed a neglected yet potentially fruitful source of material on the interaction of individual behaviour patterns.

All our pilot studies have been carried out with one strain of black hooded Norway rats. The apparatus was a 'Perspex' box 2 ft. long and 18 in. high, with lever and food tray attachments 3 in. from the caged floor of the box, which could be rearranged so that either both tray and lever were together at one end of the box (as in the early pretraining phase) or were at opposite ends (as in the experimental situation). Each single depression of the lever delivered one small pellet of the animals' standard diet into the food tray.

Initially, we used groups of three rats which had been individually trained, and recorded that after an average of four trials of 30 min a "division of labour" similar to that reported by Mowrer could be observed. The development of one such hierarchy in terms of the number of lever pressings per subject per 30 min experimental session is typically presented in Fig. 1. Our next step was to set up a series of experiments to investigate the effect of variables which might both account for and/or influence this type of group structure; for example, the variables age, sex, group size (from 2 to 5 subjects), whether the groups were littermates or non-littermates and the effect of equating the three rats of a group for size, weight and standard of performance reached during the individual training stage. In all these experiments "hierarchies" of performance emerged which were very similar to those observed in the initial series.

Fig. 1. Number of lever pressings per subject per 30 min session.

In addition, the same order of performance was maintained in all experiments throughout their duration, that is, most of these were run for 30 min a day, for 12 days. Similarly, the same structure was maintained on a series of retest trials after a lapse of several weeks.

Another series of experiments aimed at manipulating the organization itself. This series arose primarily as a means of trying to find answers to two main questions. First, what makes one animal start regularly pressing the lever? Second, what maintains this animal in its level of performance when so little food is forthcoming? One way of looking at the first of these questions was to deprive

members of a group of food differentially during the individual training stage, and alternatively, after a "hierarchy" had been formed. Another way was to use different schedules of reinforcement for the three animals during the individual training stage. Using six groups of animals for each condition we were unable to demonstrate any clear relationship between either the degree of hunger deprivation, or different schedules of reinforcement, and lever pressing performance during experimental sessions.

Further, it was of obvious general interest to observe the effects of running groups of three worker rats together and groups of three non-workers (or "parasites" in Mowrer's terminology). Again, these groups formed similar hierarchies of performance, the main difference between them being that the worker groups were much faster in all activities than the non-worker groups. When all these animals were subsequently retested in their original groups they behaved as in their initial experiments. This raised the interesting question of group membership, that is, whether animals adopted and maintained a status within their particular experimental group which is a result of the interaction between three particular rats. One way of testing this was to observe whether a rat would behave as a worker in one group, in one series of trials, and as a non-worker in a parallel series of trials. We did in fact observe this situation in several groups of animals of both sexes. Specific group membership then does appear to play a part in the formation of this type of social organization.

Finally, we have investigated the effect of training our animals in groups from the start, instead of using an initial individual training stage. Three main general conclusions emerged: (a) group training took appreciably less time than individual training to reach a comparable performance; (b) we observed the same sort of group structure as observed in the other experiments; but (c) that the structure appeared to be more flexible to the extent that a second animal in an experiment sometimes took over the bulk of the work load after a few trials. In other words it looked as though group trained animals did not develop such a fixed structure of performance for any particular group as did individually trained animals. In all other respects, however, they looked very similar.

The situation we have been investigating has in general proved flexible enough to raise a whole variety of questions relating to experimental studies of social behaviour in the laboratory. One factor which has struck us most forcibly in all our experiments is just how difficult it is to interpret our results within any general framework of social behaviour. Terms like co-operation and dominance-submission appear to have no useful application as yet. One of the most interesting aspects of this work is that it has led us to re-examine some of the terminology used to describe and explain social behaviour with respect to this and other animals. On the other hand, by careful examination of individual performances in a large number of experiments before training we have been able to make successful predictions about the status of individual members within our group situation. Worker animals, for instance, seem to be characterized at the early training stage by a greater activity and speed with which they learn and perform the task.

We hope that further investigation of this sort may point the way to an explanation of rat behaviour in group situations and thus indicate something of the quality of their adaptive capacity in social learning situations.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, February 6

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. Gottmann (Paris): "The Growing City as a Social and Political Process. I, City Form and Function in a Changing Society".\*

ROYAL INSTITUTION, LIBRARY CIRCLE (at 21 Albemarle Street, London, W.1), at 6 p.m.—Dr. H. D. Anthony: "The Study of Scenery—2".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. Emil Kekich: "Commerce" (last of four Cantor Lectures on "Some Aspects of the U.S.A. To-day").

UNIVERSITY OF LONDON (at Bedford College, Regent's Park, London, N.W.1), at 6 p.m.—Prof. A. Williams: "British Ordovician Shelly Faunas. I, Paleogeographic Setting and the Principal Faunas".\*

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. B. J. Hardy: "Some Problems in the Design and Use of Power Cables".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION, AND THE INDUSTRIAL MARKETING RESEARCH ASSOCIATION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. J. A. Nicoll: "A Technique of Long Term Forecasting"; Mr. B. N. P. Hutcheon: "Market Research—Forecasting for the Chemical Industry".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Dr. Alwyn A. Ruddock: "The Earliest English Voyagers Across the North Atlantic".

## Tuesday, February 7

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY (at Manresa Road, London, S.W.3), at 5.30 p.m.—Prof. P. M. S. Blackett, F.R.S.: "Continental Drift".

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Dr. S. W. A. Kuper: "Malignant Cells in Tissue Fluids". (Eighth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

UNIVERSITY OF LONDON (at Bedford College, Regent's Park, London, N.W.1), at 6 p.m.—Prof. A. Williams: "British Ordovician Shelly Faunas. II, Faunal Distributions in Time and Space".\*

SOCIETY OF CHEMICAL INDUSTRY, OILS AND FATS GROUP (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Prof. A. T. James: "The Biosynthesis of Unsaturated Fatty Acids by Higher and Lower Plants".

PLASTICS INSTITUTE, LONDON SECTION (at Imperial Chemical House, Millbank, London, S.W.1), at 6.30 p.m.—Mr. E. W. Langley: "Hazards and Dangers in the Plastics Industry".

## Wednesday, February 8

PLASTICS INSTITUTE (at the Institution of the Rubber Industry, 4 Kensington Palace Gardens, London, W.8), at 2.30 p.m.—Mr. R. A. Horsley: "Environmental Stress Cracking".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—The Earl of Halsbury: "The Effects of Decimalization of the Currency".

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W.3), at 5 p.m.—Dr. S. W. A. Kuper: "The Laboratory Diagnosis of Bronchial Carcinoma".\*

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. Gottman (Paris): "The Growing City as a Social and Political Process. II, The Bonds of Scale and Density".\*

SOCIETY OF ENVIRONMENTAL ENGINEERS (in the Mechanical Engineering Department, Imperial College, Exhibition Road, London, S.W.7), at 6 p.m.—Dr. P. Grootenhuys: "The Use of Visco-Elastic Materials to Control Vibrations".

SOCIETY OF INSTRUMENT TECHNOLOGY, AUTOMATION COMMITTEE (at Manson House, 26 Portland Place, London, W.1), at 6 p.m.—Mr. A. H. Parker: "Automatic Testing Applied to Aircraft Electronic Systems"; Mr. E. S. Rothery: "Techniques of Satellite Launcher Checkout".

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP—NUTRITION PANEL (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Dr. P. P. Scott: "The Nutritional Requirements of Domestic Animals".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Brunel University, Woodlands Avenue, London, W.3), at 6.30 p.m.—Mr. H. A. Codd: "Digital Computers in Road Traffic Control".

## Thursday, February 9

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.20 p.m.—Mr. J. B. Roberts: "Monte Carlo Methods for Solving Random Vibration Problems".\*

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. P. H. Fowler, F.R.S.: "The Charge Spectrum of the Primary Cosmic Radiation".\*

INSTITUTE OF PETROLEUM, ECONOMICS AND OPERATIONS GROUP (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. P. J. Dickinson: "The Japanese Oil Industry".

UNIVERSITY OF LONDON (at the Institute of Child Health, London, W.C.1), at 5.30 p.m.—Dr. K. Hellmann: "Naturally Occurring Anticoagulants and Fibrinolysins". (Ninth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

UNIVERSITY OF LONDON (in the Engineering Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. P. N. Rowe: "Engineering Research and Undergraduate Teaching" (Inaugural Lecture).\*

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (joint meeting with the Liverpool Section, in the Department of Metallurgy, The University, Liverpool), at 7 p.m.—Mr. D. J. H. Sandford: "Plastics Applications in the Motor Industry".

## Friday, February 10

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W.1), at 1 p.m.—Prof. J. N. Murrell: "Theoretical Aspects of Photochemistry".

UNIVERSITY OF LONDON (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. K. H. Jackson: "Some Features of the Gaelic Place-Names in Britain".\*

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. J. A. Fraser Roberts, F.R.S.: "Genetic Advice to Patients".

## Saturday, February 11

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. Alfreid Leutscher: "Epping Forest—Its History and Wildlife".\*

BRITISH MICROCIRCULATION SOCIETY (at the Royal Postgraduate Medical School, Du Cane Road, London, W.12), from 11 a.m. to 6 p.m.—Papers in the general fields of Microcirculation and Biorheology.

## Monday, February 13

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (joint meeting with the Colloid and Surface Chemistry Group, at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Prof. A. E. Alexander: "The Role of the Surfactant in Heterogeneous Polymerization".

UNIVERSITY OF LONDON (at Bedford College, Regent's Park, London, N.W.1), at 6 p.m.—Prof. A. Williams: "British Ordovician Shelly Faunas. III, Implications of Faunal Distributions".\*

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W.3), at 6.15 p.m.—Dr. M. K. Towers: "Cardioversion and Control of Arrhythmias".\*

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER IN INORGANIC CHEMISTRY—The Registrar, The University, Manchester 13, quoting Ref. 6/87 (February 10).

LECTURER (preferably particularly interested in the fields of power electronics, applied mechanics or hydraulics) IN ENGINEERING SCIENCE—The Registrar, University of Durham, Old Shire Hall, Durham (February 10).

LECTURER (man or woman, experienced educational psychologist) IN EDUCATION—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (February 11).

LECTURER (with good academic qualifications in biology, successful teaching experience and preferably a research degree in education) IN EDUCATION—The Registrar, The University, Liverpool (February 11).

SENIOR RESEARCH FELLOW IN AGRICULTURAL SCIENCE IN THE DEPARTMENT OF BIOLOGY to undertake and supervise research into biological problems of direct relevance to the establishment, maintenance, and utilization of improved grassland on hill farms in the Lancaster region—The Secretary, University of Lancaster, Bailrigg, Lancaster, quoting Ref. L. 199, C (February 11).

LECTURER OR ASSISTANT LECTURER IN THE DEPARTMENT OF PHILOSOPHY—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (February 13).

DIRECTOR (with special interests in fisheries research) of the Institute of Marine Biology and Oceanography, Fourah Bay College, The University College of Sierra Leone—The Inter-University Council, 33 Bedford Place, London, W.C.1 (February 15).

LECTURER (with postgraduate experience in the theory of electrical or optical properties of solids, or in elementary particle theory) IN PHYSICS—The Deputy College Secretary, Westfield College (University of London), Kidderpore Avenue, Hampstead, London, N.W.3 (February 15).

LECTURER IN SOCIOLOGY—The Secretary of the University Court, The University, Glasgow (February 18).

ASSISTANT LECTURER OR LECTURER (preferably specialized in the field of insect physiology) IN ZOOLOGY—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (February 20).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS (preferably with the degree of Ph.D. or equivalent research experience and normally below the age of 30) IN CHEMISTRY, PHYSICS, ENGINEERING (including chemical engineering), METALLURGY, PHARMACOLOGY or related subjects—The Registrar, The University, Sheffield, 10 (February 20).

LECTURER (preferably with relevant teaching experience) IN SOCIOLOGY OF EDUCATION—The Secretary, University of London Institute of Education, Malet Street, London, W.C.1 (February 20).

LECTURER (with teaching experience, good academic qualifications in physics, and preferably a higher degree in education) IN EDUCATION—The Registrar, The University, Keele, Staffordshire (February 20).

LECTURER IN GEOGRAPHY—The Secretary, The Queen's University, Belfast, Northern Ireland (February 22).

LECTURERS OR ASSISTANT LECTURERS (2) IN PHYSICS (for one of these posts applicants should have research experience in low temperature physics)—The Registrar, The University, Nottingham (February 22).

READER OR SENIOR LECTURER (with a higher degree in mathematics, experience in university teaching and research, and with special interests in either pure mathematics or applied mathematics) IN MATHEMATICS at the University College of Townsville, University of Queensland—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Townsville, February 24).

LECTURER IN THE DEPARTMENT OF CHEMICAL ENGINEERING—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (February 25).

LECTURER (with a good honours degree and experience in one of the following areas: theory or application of microwave semi-conductor devices, electromagnetic wave propagation as applied to waveguides or antennas, radar systems) IN THE DEPARTMENT OF ELECTRICAL AND ELECTRONIC ENGINEERING—The Registrar, The University, Leeds, 2 (February 27).

ASSISTANT LECTURER IN GENETICS—The Secretary, The Queen's University, Belfast, Northern Ireland (February 28).

BIOMETRICIAN (recent graduate in mathematics or statistics interested in probability theory, statistics, numerical analysis and computer science) to assist in the design of experiments and the analysis and interpretation of data—The Secretary, Institute for Research on Animal Diseases, A.R.C., Compton, Newbury, Berkshire (February 28).

LECTURER IN MEDICAL STATISTICS—Dr. Alice Stewart, Unit of Social Medicine, University of Oxford, 8 Keble Road, Oxford (February 28).

SENIOR LECTURER OF LECTURER (veterinary surgeon) in the DEPARTMENT OF VETERINARY ANATOMY—The Secretary, Royal Veterinary College (University of London), Royal College Street, London, N.W.1 (February 28).

SENIOR RESEARCH FELLOW (with a veterinary qualification) to join a team undertaking research into respiratory diseases of poultry in a new building at the Veterinary Field Station in Wirral, Cheshire—The Registrar, The University, Liverpool, 3, quoting Ref. RV/387 (March 1).

LECTURER (qualified in the field of petrology) IN GEOLOGY at the University of Tasmania, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, March 3).

READER/SENIOR LECTURER IN NUMERICAL ANALYSIS in the DEPARTMENT OF MATHEMATICS—The Academic Registrar, Loughborough University of Technology, Loughborough, Leicestershire, quoting Ref. 4/G (March 9).

READER IN ANIMAL ECOLOGY in the Department of Zoology—The Secretary of Faculties, University Registry, Broad Street, Oxford (March 11).

CHAIR OF PURE MATHEMATICS at the University of Tasmania, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, March 17).

LECTURER OR ASSISTANT LECTURER in the DEPARTMENT OF BIOCHEMISTRY—The Registrar, The University, Leeds, 2 (March 31).

CHAIR OF APPLIED OPTICS in the DEPARTMENT OF APPLIED PHYSICAL SCIENCES—The Registrar (Room 39, O.R.B.), The University, Reading.

CHAIR OF SOCIAL SCIENCE AND HUMANITIES and HEAD OF THE DEPARTMENT—The Academic Registrar, The City University, St. John Street, London, E.C.1.

TEMPORARY LECTURERS (2) (pure or applied mathematicians) in the DEPARTMENT OF MATHEMATICS—The Secretary, University College London, Gower Street, London, W.C.1.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

The Gas Council. Research Communication GC 127: 57th Report of the Joint Refractories Research Committee-1965-66. Pp. 16. Research Communication GC 128: Pilot-Plant Investigations of the Desulphurisation of Light Distillates. By Dr. J. A. Lacey and S. K. Mukherjee. Pp. 14. Research Communication GC 129: Metallurgical Aspects of High-Temperature Reformer Furnace Alloys. By Dr. R. G. Baker and Dr. W. L. Mercer. Pp. 16. # Which filter paper?

The Answer is in

## "SIGNPOSTS to Better Filtration"

So send for a free copy at once, it is printed to assist chemists in the selection of filter papers. Please quote (Ref. N).

**J. BARCHAM GREEN LIMITED**  
HAYLE MILL MAIDSTONE KENT ENGLAND

## POCKET MICROSCOPE

### GOOD QUALITY OPTICS - AT A LOW COST

A compact, precision instrument, providing the performance of a good quality bench microscope for field studies.

- Magnification  $\times 100$ ,  $\times 150$ ,  $\times 200$  or  $\times 300$  to choice
- Standard eyepiece and objectives
- 160 mm tube length
- Weight 500g. Size  $9 \times 11 \times 4$  cm.
- Inclined ocular for easy viewing
- Strong steel case with tripod socket

Further details sent on request :

**POLARON**  
EQUIPMENT LTD.

4 Shakespeare Road,  
Finchley, London, N.3  
Telephone: VIRginia 9241

## The Memory System of the Brain

J. Z. YOUNG

This book explores the useful analogy that may be drawn between brain and computer. From work on the octopus the author develops the idea that systems of a few cells may be the basic units of memory, each storing one new 'bit' of information. 32 text figures 28s net

## Atomism in England from Harriot to Newton

ROBERT HUGH KARGON

The author traces the history of the introduction and spread of the atomic doctrine as a case study of the problems of the establishment of the new learning and its methodology. He includes studies of the theories and methods of Harriot, Bacon, Hobbes, Boyle and Newton, as well as of the lesser figures who were historically so important. 42s net

## Principles of Physical Chemistry for Biology and Pharmacy

L. SAUNDERS

An introduction to physical chemistry for students reading for degrees in pharmacy and biological sciences, this book should also interest other chemistry students, since mathematical aspects are developed step by step. Numerous text figures 63s net

## Growth, Function and Regulation in Bacterial Cells

A. C. R. DEAN and  
CYRIL HINSHELWOOD

The authors discuss the need for coordination of the great modern advances in detailed knowledge of biochemical reactions, in the structure of 'biological' macromolecules, and in bacterial genetics, in the light of general laws and of experimental researches on the growth, function and regulation of bacterial cells when regarded as complete entities. 2 plates, 121 text figures 84s net

### Classified Advertisements

Semi-displayed £4 16s. per single column inch. Minimum £2, each additional 1/12th of an inch 8s. Full page £132. Half page across £66. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: HOLborn 4743. Telegrams: Textualist, London, W.C.2.

### APPOINTMENTS VACANT

#### UNIVERSITY OF LEEDS THE ASTBURY DEPARTMENT OF BIOPHYSICS

Applications are invited for the post of Assistant Lecturer or Lecturer to assist in the teaching of the physical chemistry of biological macromolecules and to carry out research in this general field. Applicants must be chemists or physicists with experience of biological macromolecules. The post is tenable immediately but the starting date could be postponed until October 1 if necessary. The successful applicant will be required to assist in teaching to undergraduates and to postgraduate students but ample time will be provided for research in a new building (occupation date June, 1968) with modern equipment. Salary on the scale £1,105 to £1,340 for an Assistant Lecturer or £1,470 to £2,630 (efficiency bar £2,270) for a Lecturer.

Applications (three copies), stating age, qualifications and experience and the names of three referees, should reach the Registrar, the University, Leeds, 2 (from whom further particulars may be obtained) not later than February 28, 1967. (469)

#### UNIVERSITY OF STRATHCLYDE

#### DEPARTMENT OF NATURAL PHILOSOPHY

#### LECTURESHIP

Applications are invited from physicists with theoretical or experimental research interests in plasma physics or lasers for appointment as LECTURER in the Department of Natural Philosophy.

The successful candidate will be required to take part in undergraduate teaching and to participate in the programme of research in the Department.

Salary scale: £1,470 to £2,630 per annum plus F.S.S.U. with placing according to experience and qualifications.

Application forms and further particulars (quoting 2/67), can be obtained from the Registrar, University of Strathclyde, George Street, Glasgow, C.1, with whom applications should be lodged by February 28, 1967. (476)

#### UNIVERSITY OF WATERLOO DEPARTMENT OF BIOLOGY WATERLOO, ONTARIO, CANADA

Applications are invited from students for post-graduate studies leading to M.Sc. or Ph.D. Areas of research include freshwater biology, taxonomy, microbiology, physiology, genetics, and palynology. Teaching Fellowships to the value of \$2,600 for 8-month academic year, plus summer stipend of \$1,000 available.

DR. H. B. N. HYNES,  
Chairman. (346)

SCIENTIFIC INFORMATION OFFICER with degree in agriculture or related subject and a flair for languages, including English, required to join a team engaged in publishing the latest research findings on temperate and tropical grasslands and annual field crops in two journals of international repute. Salary in scale £926 to £2,431. F.S.S.U., canteen, 5-day week.—For application form apply to Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, nr. Maidenhead, Berks. (336)

## THE IMPERIAL TOBACCO COMPANY

has a vacancy in its Research Department in Bristol for a

## PHYSICIST

to join a team working on problems concerned with the measurement of the particle size and structure of tobacco smoke aerosol, and with phenomena associated with its deposition on solid surfaces.

Applications, which will be treated in confidence, are invited from Physicists between 21 and 28 years old, with an Honours Degree or equivalent qualification.

Apply to:

STAFF SECRETARY,  
IMPERIAL TOBACCO CO. LTD.,  
BRISTOL 3.

(519)

## FOREST ENTOMOLOGISTS AND TOXICOLOGISTS

### DEPARTMENT OF FORESTRY VARIOUS CENTRES ACROSS CANADA

A number of entomologists are needed to meet the requirements of a rapidly growing forest research organization. Current opportunities are for scientists trained in insect cytology, genetics, physiology, ecology and toxicology (which includes basic studies on insecticidal residues and the mode of action of systemic insecticides).

Candidates should have an advanced degree and related experience. Opportunities for salary advancement are excellent.

Résumés should be submitted to the  
Civil Service Commission, Ottawa 4, Canada,  
quoting file reference 66-100-DF. Interviews may  
be arranged in the U.K. for February-March, 1967.

(560)

## NORTH OF ENGLAND ZOOLOGICAL SOCIETY

Zoological Gardens, Chester

Applications are invited for the position of full-time

## Veterinary Surgeon

to the above Society, which is recognised as one of the leading Zoos of the world.

The successful applicant must be interested in all types of livestock and have a knowledge of dietetics. New Laboratory with facilities for research. Excellent opportunity for newly-qualified Veterinary Surgeon. Salary commensurate with qualifications, age and experience. Superannuation Scheme. House provided.

Applications in writing, together with copies of three recent testimonials should be submitted to the Director-Secretary, North of England Zoological Society Zoological Gardens, Chester, to arrive not later than SATURDAY, FEBRUARY 25, 1967.

(530)

# Pharmaceutical Research

The Research Division of Pfizer Limited already employs some 500 scientists and technicians from many different scientific disciplines, and the current research effort in the United Kingdom is running at an expenditure in excess of £1,000,000 per annum. The Departments of Chemistry and Biochemistry now have a number of additional vacancies.

## **GRADUATE BIOCHEMIST TO UNDERTAKE STUDIES ON DRUG METABOLISM**

This appointment calls for a scientist with some experience, preferably in this field, although we would welcome inquiries from graduates with experience in related fields, e.g. metabolic pathway studies. Technical assistants will be provided. In addition the person appointed will supervise the work of the Analytical Services Section in the Biochemical Research Department.

## **TECHNICIAN FOR DRUG METABOLISM STUDIES**

The successful applicant will have had a number of years' experience in a similar field and be familiar with analytical, biochemical or drug metabolism techniques.

## **SENIOR TECHNICIAN, ANALYTICAL SERVICES SECTION, BIOCHEMICAL RESEARCH DEPARTMENT**

This services section provides a radiochemical counting and analytical service to the Project teams within the department. Applicants must be conversant with modern techniques and equipment and fully experienced in the use of automatic liquid scintillation counters.

## **TECHNICIANS FOR CHEMICAL RESEARCH**

These vacancies are particularly suitable for technicians who are currently studying for H.N.C. and who have an interest in organic synthesis.

In every instance, the opportunities offer real prospects of career advancement, and facilities are available for the obtaining of further academic qualifications.

The salaries offered, whilst being dependent upon qualifications, experience and age, will be competitive and the fringe benefits include free pension and life assurance schemes, profit sharing bonus scheme, payment of removal expenses (if appropriate), etc.

Applications, which will be treated in the strictest confidence, should be addressed to:

**The Personnel Manager,  
Research Division,  
PFIZER LIMITED,  
Sandwich, Kent.**

## CHIEF BOTANIST

NATIONAL MUSEUM OF CANADA  
OTTAWA, CANADA

The scientist appointed to this position will have overall responsibilities for the National Herbarium and botanical laboratories. He will supervise research programs being undertaken in systematic botany, review the grants-in-aid program of the National Herbarium to botanists at universities and participate in the educational program provided by the Museum. Some field work may be required in relation to the Chief Botanist's personal research program.

Applicants must have a Ph.D. in botany, a number of years of research experience in systematic botany and some administrative experience. It is expected that this appointment will be made in the salary range \$14,000-\$20,000.

Résumés should be submitted to the  
Bio-Physical Sciences Program,  
Civil Service Commission, Ottawa 4, Canada,  
quoting file reference 67-100BB.  
Further details are available on request.

(524)

## ROYAL HOLLOWAY COLLEGE

(University of London)

Englefield Green, Surrey

Applications are invited for the following academic appointments from October 1, 1967:

### MATHEMATICS

Lecturers or Assistant Lecturers in Pure or Applied Mathematics, preferably with research interests in Algebra, Analysis, or Quantum Theory.

### STATISTICS

Lecturer or Assistant Lecturer.

### COMPUTER SCIENCE

Lecturer or Assistant Lecturer with research interests in Computer Science.

### ENGLISH

Lecturer in English Literature. Interest in Shakespeare essential.

Salary scale for Lecturers, £1,470 to £2,630; and for Assistant Lecturers, £1,105 to £1,340.

Further details may be obtained from the College Secretary. Applications (6 copies, please), together with the names and addresses of two referees, should reach him by February 25, 1967. (518)

## AGRICULTURAL RESEARCH COUNCIL OF CENTRAL AFRICA

### SENIOR RESEARCH ENTOMOLOGIST RESEARCH ENTOMOLOGIST

For research in Biological Control of Tsetse Flies by the Method of Sterile Male Release

An A.R.C.C.A. research group of five graduates with a strong supporting staff and good field facilities has been working for the past three years, together with a team seconded from the U.S.D.A., on the field and laboratory development of this new technique. Both chemosterilant and radiosterilant treatments have been successfully proved and the project is at the Pilot Scheme stage on an island at Lake Kariba. There will shortly be a vacancy for an experienced research glossinologist in this group. Salary in the Principle Research Officer scale £2,136 to £3,000 according to qualifications and experience. An appointment may be offered in a higher scale for candidates of exceptional accomplishments. A three-year contract is offered with family return fares and mid-tour leave to Cape Town. A secondment for a shorter period of not less than a year would be considered. The post is available from March 1, 1967.

A vacancy will also occur for a newly qualified research entomologist to join this team at M.Sc. or Ph.D. level.

There are no application forms, but career details and the names of three referees should be sent to one of the undermentioned addresses:

The Secretary, Agricultural Research Council of Central Africa,  
P.O. Box 3397, Salisbury, Rhodesia. P.O. Box 215, Lilongwe, Malawi. P.O. Box 2218, Lusaka, Zambia. (X438)

## RESEARCH ASSISTANTSHIPS IN PHYSIOLOGY

Applications are invited for RESEARCH ASSISTANTSHIPS from qualified students wishing to work towards the M.Sc. or Ph.D. degrees. Stipend range \$2,300 to \$3,600 per annum.

Write for further information to: Dr. D. H. Copp, Head, Department of Physiology, University of British Columbia, Vancouver 8, B.C., Canada. (341)

## UNIVERSITY OF STRATHCLYDE

THE ANDERSONIAN LIBRARY

SUB-LIBRARIAN

Applications are invited for the above post from Honours graduates with a Librarianship qualification, preferably experienced in the field of Science and Technology.

Lecturing ability on aspects of Information Retrieval and a capacity for Readers' Adviser work essential.

Salary scale: £1,470 by £90 to £2,010 by £85 to £2,180 by £90 to £2,630 per annum, with F.S.S.U. benefits.

Forms of application (quoting 11/67), can be obtained from the Registrar, University of Strathclyde, George Street, Glasgow, C.1. (475)

## UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF METALLURGY

LECTURESHIP IN CHEMICAL  
METALLURGY

Applications are invited for a Lectureship in Chemical Metallurgy in the Department of Metallurgy. Candidates should be Physical Chemists with an interest in Thermodynamics and Electrochemistry and should be willing to develop those interests within the context of Extraction Metallurgy. There is an active Research School and the successful applicant would be expected to carry out and supervise research in this field.

Salary scale: £1,470 to £2,630 per annum plus F.S.S.U.

Application forms and further particulars (quoting 73/66), can be obtained from the Registrar, University of Strathclyde, George Street, Glasgow, C.1, with whom applications should be lodged by February 11, 1967. (477)

## UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE

DEPARTMENT OF CHEMISTRY

Applications are invited for the post of ASSISTANT LECTURER in the Department of Chemistry. Candidates should have research experience either in inorganic chemistry or in physical chemistry. Salary scale according to age and experience in the range £1,105 by £1,340.

Applications, together with the names of three referees, should reach the Registrar, University College, Cathays Park, Cardiff, from whom further particulars may be obtained, by February 15, 1967. (359)

## UNIVERSITY OF READING

RESEARCH ASSISTANT required in high pressure/high temperature experimental unit Geology Department. Honours degree in Geology or Chemistry. No previous experimental petrology experience necessary but an interest in crystalline rocks and/or phase equilibria studies essential. The Assistant will carry out research towards a higher degree. Salary £600 by £25 to £650 per annum.

Write, quoting M3 to Assistant Bursar (Personnel), University of Reading, Berkshire. (452)

## NO MONEY TO SPEND

NOBODY can say that Mr. Johnson's budget for the coming fiscal year is calculated to win friends among scientists in the United States. It is much more likely to increase the irritation of those who have been saying, for several months now, that too much of the federal government's support for scientific activities of one kind or another is being spent on the attainment—and even, occasionally, the failure to attain—short term objectives. Congress is accustomed to deal more harshly with civil than with military projects in research and development. The Department of Defense can usually get a fair wind for the development of a new missile, but the Mohole project can be cancelled after a few desultory committee meetings. (Whatever the faults of Mohole may have been, it should now be clear that Congress would have been wiser to find some other way of saving money than to assume direct control of the affairs of what should be an independent agency.) Then there are the figures which show that expenditure on research and development in the United States has now decisively levelled off. Between 1967 and 1968, the budget estimates for military research and development amount to an increase of 7.2 per cent, but the amount to be spent on civil activities (including space flight) will be almost unchanged. In the circumstances it is no wonder that the physicists have taken a somewhat masochistic pleasure in pointing out (*Physics Today*, 20, 99; 1967) that the trend of expenditure on research in physics now lags a long way behind the target the physicists were encouraged to design for themselves only a year ago.

But what is to be done? There are two issues to be decided—the level of expenditure on research and development appropriate to an advanced society like that in the United States, and the proportion of this that should be spent on basic research. So far there are only rules of thumb and the dictates of arbitrary shifts of public policy to decide how much to spend and where. Even expenditure on military research and development is not as direct a consequence of what the military planners consider to be military necessity as they would like to think. A great many projects, for example, cannot be attempted for lack of men. For the research and development budget as a whole, men and their availability are also crucial. The host of decisions which go to make up a complete budget of the kind now published in the United States is tantamount to a decision about what proportion of the country's skilled manpower can be devoted to creative research and development. In the circumstances, it is meaningful to protest that the administration may have made wrong choices about the allocation of its resources. In the United States, it is remarkable how many of the projects now being undertaken in the belief that they will bring industrial advancement of some kind or another are being financed from federal money.

Why cannot industrialists make their own decisions in these matters? On basic research, the best criterion so far for deciding how much should be spent is that there should be enough to keep educators enlivened and their students provided with problems on which to cut their teeth. One of the cogent objections to the present arrangements for financing basic civil research in the United States is that a large proportion of the money available comes from what are called mission-oriented agencies. In the nature of things, these are not equipped to make disinterested decisions about the pattern of work and education in universities and similar establishments. It could not fail to be a benefit if some of their largesse were channelled through institutions like the National Science Foundation more able to keep closely in touch with what is happening in the laboratories. That way, there might be less complaint and, more important, some hope of constructing the volume of case-law necessary if objective yardsticks about the pattern of spending are eventually to be designed.

## CLOSING THE STABLE DOOR

THE statement on information exchange groups by the Commission of Biological Editors which appears on page 547 is reasonable and predictable, if a little late in the day. It amounts to a declaration of contrary interest by an influential group of biological journals. If the IEG scheme had still been in full flood, this statement would have given the organizers and the members cause to reconsider what they were about. In the event, the National Institutes of Health have had the good sense to see that the experiment could not flourish without creating contradiction, and the groups are to be discontinued. That is a welcome development, but it does not follow that the statement is redundant. The horse may never have the strength to bolt, but it is only sensible to shut the stable door. The statement will put clearly on record the case for hoping that other experiments similar to IEG will not in future be attempted. It will also draw attention to the need for channels of communication in science with those attributes which made the IEG experiment attractive. Because the IEG seem to be coming to an end, there is no case for treating the long-term questions less urgently.

The case against IEG is now familiar, and needs no rehearsal. The biological editors are wise, however, to work from the assumption that the activities of the exchange groups were indistinguishable from publication in the more orthodox sense. There is no point in beating about that bush. Publication is broadcast writing, and the circulation of preprints to the large and often anonymous membership of some of the exchange

groups is publication in every sense that matters. The fact that IEG communications are circulated only within a chosen circle is no defence against the charge of publication but merely evidence that the method of publication is defective. Certainly the methods of the IEG are enough like publication to make a mockery of the phrase "personal communication" used as a euphemism in referring to information gleaned from circulating preprints. The biological editors would have been within their rights if they had insisted on some demeaning alternative to distinguish the communications of the IEG from the personal letters which are a traditional part of scholarship of all kinds—"impersonal communication", perhaps, or "postal circular". Certainly they are on safe ground, and they will carry most working scientists with them, in saying that they have no wish to connive at multiple publication. That is the essence of their case against the IEG.

The question will arise of where *Nature* stands, and it should be plain already that this journal has the fullest sympathy with the statement which the biological editors have put out. But the rules which the biological editors have drafted are not easily applicable to journals like this. For one thing, there is no regular means by which a general journal can know what is circulating on the IEG network. Indeed, even the journals which have decided to adhere to the statement by the biological editors can only hope consistently to enforce their own rules through the supposedly secret knowledge of people who are also on the books of the IEG. It is also important that *Nature* has a special interest in publishing material which commands attention outside the branch of science with which it is chiefly concerned, so that the region of potential conflict with the IEG (which must be narrowly defined if they are to function at all) should be less serious than for most journals. At the same time, a journal like this, whose function is in part to provide working scientists with a sense that they know what is going on, cannot wholeheartedly endorse the view that the IEG would be unobjectionable if they circulated "very brief notices of current research". The truth is that preliminary accounts of research in progress are as much in need of publication for the world to see as are the more formal contributions to the literature. But all this raises a host of almost legalistic questions. In the long run, the only defence is to beat the IEG at their own game. Fortunately, there is every reason to expect that about the middle of this year, *Nature* will be operating consistently with a time lag of a few weeks, and without skimping on the care spent in sending communications to referees. It will be harder for monthly journals to follow suit, but obviously they should try.

Improving the service which the journals provide is obviously important, and the statement by the biological editors draws attention to some of the more obvious steps which could be taken, although there is a good chance that many of the common complaints against the journals would melt away if more of them had full-time technical assistance. But mere mechan-

ical improvements are not enough. One of the most serious defects of the published literature is that it has become obsessively concerned with the compilation of a historical record, and too little concerned with communicating ideas and information in such a way as to refresh and to enliven. Indeed, one of the reasons that the IEG system has given such offence to the established journals is the implication that material sent for publication would be brought by some other means to the attention of those most likely to find it interesting. In part, of course, the fault lies with the journals, which have often taken too solemn a view of their function. Fortunately, they have it in their own power to decide whether the literature is to be read now or only by posterity.

## MANNING THE COMPUTERS

THE advice which the British Government has been given on the training of people to run computers is probably sound but certainly unimaginative (see page 539). It is comforting, of course, to know that there is not much reason to worry about the training for the less demanding jobs—operating computers and writing programmes for them. The computer manufacturers will look after that. But the advice which the working group at the Department of Education and Science has provided on the impending shortage of systems analysts and systems designers, as they are called, is much less convincing. The working party may be right, but its arguments are a little pedestrian and therefore unconvincing.

The immediate problem is to know precisely what is meant by a systems analyst or designer. The working group does not help by saying that the terms are intended as a "generic rather than an exact description". The point seems to be that there is a great need among potential users of computers for men and women who can devise ways for making the best use of computers, and who can do so with such flair that they carry other people with them. Evidently, systems analysts are evidently the evangelists of the computer age. But is it not therefore in the nature of things that they will work themselves out of their jobs? Will the need of them be as conspicuous and particular when there is a more sensitive appreciation throughout British industry of the ways in which computers can bring rationality and better performance to many industrial and commercial organizations? Exact predictions are obviously impossible, but the working group may well have been too wooden in making a simple linear extrapolation into the seventies. Courses there should be, of course, but in the long run it may be more important that undergraduates in a variety of disciplines should be given an opportunity to learn at first hand what it is like to have to plan the efficient use of a large computer. The truth is that if systems analysis is as valuable as the working group believes, it should be made a leavening throughout society.

## NEWS AND VIEWS

### Natural Gas

CHOOSING an awkward moment, Phillips Petroleum Exploration have announced a new find of natural gas in the North Sea. The announcement came a few days before the Gas Council and the successful oil companies—Shell-Esso and Amoco—were due to resume negotiations about the price to be paid for the gas the companies have found. The new find, which Phillips put at  $87 \times 10^6$  cu ft per day (twice as much as from any previous find in the North Sea), may strengthen the hand of the Gas Council in the negotiations. The Chairman of the Gas Council, Sir Henry Jones, has been consistently optimistic about the amount of gas which the North Sea field would produce, and is bound to feel vindicated by this latest find. Sir Henry believes that supplies of up to  $4,000 \times 10^6$  cu ft per day may be possible if more wells are drilled; the wells already drilled, he says, could supply between  $2,500 \times 10^6$  and  $3,000 \times 10^6$  cu ft per day. The Ministry of Power still quotes a figure of  $1,000 \times 10^6$  cu ft per day, although the Phillips find may induce it to think again.

The battle over price now enters a new and fascinating phase. For the first find, by British Petroleum, the Gas Council has agreed to pay 5d. a therm (1 therm = 100 cu ft) for  $100 \times 10^6$  cu ft per day. This contract was awarded as a stop-gap measure, with an eye towards encouraging other companies to explore. Those who were encouraged would have been naive to expect comparable rewards, and in fact the original Gas Council offer to Shell-Esso and Amoco represents 1.8d. per therm for  $500 \times 10^6$  cu ft per day. This offer, described as "woefully inadequate" by an Amoco spokesman, now begins to look more reasonable. The oil companies cannot offer to sell the gas direct to industry unless they can satisfy the Ministry of Power that it has first been offered to the Area Gas Boards at a reasonable price. The minister, Mr. Richard Marsh, is presumably to be the judge of what is reasonable. In the past week, agreement on a compromise figure of between 2.25 and 2.75d. per therm has seemed likely, but price is not the only factor. The load factors of the pipelines, rate of build-up of supplies and the duration of supplies have also to be negotiated.

To compete with fuel oil, the Gas Council says that it must supply gas at the factories at a rate of 4d. a therm, which implies an onshore price of about 2d. to 3d. Low prices, it says, would provide a great stimulus to the British economy, and would help to bring down the price of other forms of energy. It points to the situation in the United States, where natural gas accounts for a quarter of heat generation, and one fifth of electricity generation, and natural gas from Texas and Louisiana sells at 1.7d. per therm. The Ministry of Power, on the other hand, has also to consider the National Coal Board, to which fears of unemployment are a powerful emotional weapon, and which is unwilling to accelerate the process of eliminating uneconomic pits. The Gas Council, however, has a final trump card; it points out that increas-

ing use of natural gas at the expense of oil would favourably affect the British balance of payments.

### Men for the Machines

THE British Government has been provided with a prediction of the balance between the supply and demand for skilled men to operate computers which is partly cheerful and partly alarming. The report of the Interdepartmental Working Group now published by the Department of Education and Science and the corresponding bodies in Scotland and Northern Ireland (*Computer Education*, H.M.S.O., 4s. 6d.) says that on present tendencies there will be a "crucial shortage" of systems analysts and systems designers in 1970. The group seems, however, to have satisfied itself that those who use and manufacture computers will be able to train on the job the programmers and machine operators they are likely to need.

The estimates of future demand are based on forward projections of the numbers of computers likely to be in service in the United Kingdom in 1970. The 1,000 computers in service in Britain in 1965 are expected to be joined by a further 2,000 by 1970. Although there is likely to be a need for an extra 19,000 programmers by 1970, the computer manufacturers trained 4,000 people in 1964, are expected to have trained 6,000 in 1966, and appear confident that they will be able to meet all foreseeable needs and also to make up for wastage. Machine operators seem equally easy to come by and to train quickly. The computer manufacturers seem also confident of being able to recruit and train the maintenance men they will need in the next few years. But where systems designers and systems analysts are concerned, the group has calculated that there will be a need for an extra 12,000 of them by 1970, and that at least 500 of those will have to be senior people. Even now, the group considers, employers are finding it so hard to recruit systems analysts that existing computers may be used less efficiently than they might be.

The potential shortage of systems analysts provides, in the language of the report, "one specific urgent call on the educational system over the next few years". The group would like to see an integrated programme of education and training with successive periods of experience at work and in full-time instruction at some college or university. It suggests that students on courses should usually be sponsored by potential computer users. The report points out that the Industrial Training Boards could do something to help, principally by providing cash incentives to industry, but it is also recognized that the training of the more senior people thought to be necessary will have to come by greater provision of postgraduate courses at universities and elsewhere. The group considered that planning of courses on this pattern, at present being discussed with universities, was a hopeful sign but was unlikely to cater for the whole demand.

In practice the group was dismayed to find that the postgraduate courses at present available with what is called a "substantial computer element" are not fully used by students. In 1965, for example, there were 165 postgraduate students on 19 courses at various universities and colleges of advanced technology. This represented an increase of nearly 25 per cent compared

with the population of these courses in 1964 but was nevertheless much less than the estimated optimum capacity of all the courses which amounted to 260 or thereabouts. Indeed, the working group has estimated that the same courses could have accommodated roughly 400 people in 1965 if they had been stretched to full capacity.

## Office for Information

SUPPORT by the British Government for the development of information services in science is growing steadily. The Office for Scientific and Technical Information (OSTI) emerged as an independent unit under the Department of Education and Science from the fragmentation of the Department of Scientific and Industrial Research in 1964-65. Last year (1966) the expenditure of the office amounted to £300,000. A scientific staff of 13 is now employed. For the time being, the office seems to have adopted as an article of faith the view that it should wherever possible work closely with similar organizations abroad and particularly in the United States. Much of its activity so far has consisted of the application to British circumstances of information services already being developed in the United States.

Most of the activity of OSTI consists of letting contracts to outside bodies. Most often this means universities, but research associations, learned societies, and industry are also eligible for assistance. As part of the plan to collaborate with information services abroad, OSTI is supporting the trial in Britain of the MEDLARS information retrieval service devised by the United States National Library of Medicine, and the corresponding system in chemistry sponsored by *Chemical Abstracts*. But the office has also helped with grants to the University of Sheffield for research on the automatic detection of structural similarities among chemical structures (£17,500 for the three years), the formation of an information centre for high temperature processes at the University of Leeds (£13,555 over three years) and what is called a National Reprographic Centre for Documentation at the Hatfield College of Technology (£32,691). The terms of reference for OSTI seem to be generously wide. They have, for example, allowed it to provide a grant for the support of *Physics Abstracts*, at present published by the Institution of Electrical Engineers. The intention is that the grant should enable the abstracting journal to investigate new techniques of compilation and dissemination. *Physics Abstracts* is also supported on a continuing basis by the United States Government by means of a grant through the American Institute of Physics.

OSTI policy is determined largely by the Advisory Committee for Scientific and Technical Information under Dr. F. S. Dainton, Vice-Chancellor of the University of Nottingham. The committee, eleven strong, consists of six academics, three industrial scientists, a librarian and an independent consultant linked with a scientific journal. The committee seems to meet about three times a year and includes assessors from other Government departments including research councils, the Ministry of Technology, and the Atomic Energy Authority. Although the committee is advisory, it has the responsibility for deciding how resources

should be divided. As yet, fortunately, the budget seems to have kept up with the flow of good ideas.

## Design for Brittle Materials

ENGINEERS have long fought shy of using brittle materials. Ductile materials are better understood, more reproducible, and have the overwhelming advantage of being able to relieve stress by expansion if the design stress is accidentally exceeded. Some brittle materials, of course, are in common use—concrete, glass, and cast iron—but they are normally used in bulk at low stress. This reluctance to use brittle materials will, however, have to be overcome, for some of them possess properties—strength at high temperatures, and corrosion resistance—which are important in hypersonic aircraft, spacecraft and gas turbines. This group of materials includes tungsten, chromium and compound materials, ceramics and glasses. A new publication by K. W. Mitchell of the Fulmer Research Institute, commissioned by the Inter-Services Metallurgical Research Council, examines the criteria for designing in brittle materials (H.M.S.O., 12s.).

If it were necessary simply to design components which will not fail under normal conditions, the problem would be relatively easy. But in practice, of course, weight and cost have also to be considered. For ductile materials, designs are commonly based on mean or average stresses calculated by normal methods of stress analysis, but for brittle materials a more detailed examination of the stress distribution is desirable since the design must provide for unexpected loads. Conventional theories of elasticity are not strictly applicable except as a first approximation, and failure stresses must be defined in terms of a statistical distribution for the material in the condition and the size needed. There is a great shortage of published information about the properties of brittle materials: companies, which have gained their knowledge by practical experience are reluctant to divulge it freely. Then little is known about the mechanism of failure of brittle components; apart from testing at constant temperature, it is necessary to examine the effect of rapid heating and cooling, which may set up thermal stresses in the material. Surface condition is also important, since surface cracks increase stresses locally. The problems of lubrication and wear resistance are mentioned in this report but not considered in detail. And throughout this field, there seems a need for more information, and not only about successful designs: reports of failures can prevent others repeating them.

## Changes at Harwell

THE United Kingdom Atomic Energy Authority, committed to diversification, is to undertake responsibility for two new research centres at Harwell. The new centres, announced on February 6 by Minister of Technology Anthony Wedgwood Benn, will be responsible for Non-Destructive Testing and Ceramics Research. When fully established the centres will cost £200,000 and £420,000 per year respectively, and five-year plans have been drawn up for both projects.

The Ceramics Research Centre is intended to help and encourage industry to make the best possible use of ceramics. Although widely used for industrial processes at high temperatures, ceramics are not well understood. The iron and steel industry uses more ceramics than most, and is likely to be the chief beneficiary if the centre can make radical improvements in manufacture, fabrication or use, but other industries also use ceramics in smaller quantities. Dr. F. J. P. Clarke of the Ceramics Division at Harwell will be the first head of the centre. Initially work will be concentrated on developing refractory oxides, and on methods of producing high quality oxide ceramics and special graphites.

THE Atlas Computer Laboratory of the Science Research Council is embarking on an experiment to test the usefulness of multiple access computer systems. According to the Science Research Council, the project will cost £95,000. By the beginning of 1968 it is planned that there shall be twenty teletype consoles linked to the Atlas computer through an intermediate satellite machine built by the General Electric Co., Ltd. (U.K.). In the planning of the experiment, careful attention is being given to the quality of the system, and the planners are particularly anxious to avoid peripheral troubles of the kind which have occasionally afflicted other multiple access systems—inadequacy of teleprinter links, for example. The satellite computer is intended to take over much of the housekeeping work associated with multiple access systems; experience with Project MAC at the Massachusetts Institute of Technology is said to have shown that roughly a third of the time spent by users of multiple access systems goes on comparatively humdrum activities such as editing and retrieving information. Obviously it is not sensible to bother the big machine with chores like these. In practice the multiple access experiment is intended to compete with the other users of the Atlas computer. At present keep that machine more than busy. Every job taken on, two are turned down. The laboratory is co-operating with International Business Machines Corp., Ltd., in a study of the problems which arise when multiple access is used by many users of the multiple access system. The Atlas laboratory is part of a group concerned with the study of the problems known as ASCOT,

The laboratory itself seems now to have settled down in the building at Culham, Berkshire, which it has occupied since the middle of 1964. At present the computer is running three shifts on five days a week and the weekends are likely to be used as well in the course of this year. The computer itself is now in service for between 95 and 98 per cent of the available time, and half of the unplanned shutdowns seem to be due to failures in the 48K core store with which the machine is provided. The experience of the past few months has shown that, in a typical week, something like 2,500 jobs may be undertaken at the laboratory. The principal customers are universities, and there are 250 university projects on the book, most of them in mathematics, the physical sciences and engineering. The laboratory also works for some industrial users and for government research laboratories. It has, for example, been concerned with numerical forecasting for the Meteorological Office.

FEDERAL support for science was the theme when Dr. Frederick Seitz, President of the National Academy of Sciences, dedicated the Space Sciences Building at the University of Arizona in Tucson. Dr. Seitz gave the impression that research workers were beginning to go short of money, and the war in Vietnam was not the only reason for this. For a start, expenditure on basic science was not growing at the rate of 15 per cent per year which many people felt was necessary. The figure of 15 per cent, he said, applied only to basic sciences, and only for a limited period, perhaps a decade or so more.

The second difficulty was that of big science. The Mohole project, said Dr. Seitz, had been scientifically sound, but had been cancelled because of the escalation of costs and the intrusion of political issues. Dr. Seitz said that he hoped the project would be reinstated; a permanent restriction on deep-sea drilling would not serve the interests of science. As for the 200 GeV accelerator, which scientists in the United States had asked for, Congress had not yet felt ready to act, while in the U.S.S.R. a 70 GeV accelerator was almost finished and in Europe a 300 GeV machine seriously contemplated. If the decision on the American machine were delayed beyond 1967, the position of the United States in high energy physics would be put in serious jeopardy.

A third factor, according to Dr. Seitz, was the growing geographical concentration of scientific expenditure. Centres of excellence, he implied, carried with them their own dangers in a country in which so many decisions are made on the basis of proportional representation. "It is difficult to believe that Congress will agree indefinitely both to expand the budgets for science and to concentrate the money increasingly in a few geographical areas." Congress might well take the matter of geographical distribution into its own hands. On space research, Dr. Seitz hoped that the frenzied atmosphere of competition could be replaced by some form of international co-operation to ensure that the scientific aspects of the exploration could be handled in a less peripheral way.

## More about Mohole

THE complaint about the way in which the U.S. Congress has cut off Project Mohole without a shilling is also one of the themes of the annual report of the President of the Carnegie Institution, Mr. Caryl P. Haskins, for 1965-66. Mr. Haskins pointed to the way in which the federal government has grown to be a dominant influence in the sponsorship of research, and to the way in which a situation of this kind has arisen. Policy will become a matter for "public and indeed political judgment and decision". Mr. Haskins said that the dangers had become particularly acute in 1966 and that the way in which the Appropriations Committee of the House of Representatives had refused the National Science Foundation \$19.7 million for Project Mohole was ominous. For one thing, he said, there has been financial loss as a result of the cancellation but, more important, real damage has also been done to the pattern of research in the United States. Although Mohole had begun badly, it had "recently been much more consistently planned". Mr. Haskins also complained at the way in which the National Science Foundation has repeatedly been denied by Congress the sums of money for which it asked in its budget. The foundation, he said, is the only agency of the government free to put its resources where they can be best applied.

## Trouble about Stonehenge

ASTRO-ARCHAEOLOGISTS seem to be a quarrelsome lot. The controversy in *Nature* about whether Stonehenge was a computer for predicting eclipses, and if so what kind of computer, has been sustained ever since the publication by Professor Gerald S. Hawkins of an article on the subject in 1963 (*Nature*, 200, 306). Last week, for example, Drs. Cotton and Martin from the University of Melbourne argued that Professor Hawkins's scheme, like that of Professor Hoyle, is too elaborate. But Professor Hawkins himself (Smithsonian Institution Astrophysical Observatory, Special Report 226) has now taken Sir Norman Lockyer to task for having published "Some Questions for Archaeologists" in 1906 (*Nature*, 73, 280) which, so Hawkins says, "should never have been permitted into print by the editor of *Nature* who was at that time Sir Norman himself". Hawkins goes on to refer to Lockyer's other work on Egyptian chronology, mythology, religion and the calendar, and says: "Such an extensive effort was premature, and he did not proceed at an appropriate scholastic pace by publishing step by step in the scientific journals and thus benefiting from the appraisal and criticism of other scholars." Despite the unfortunate context in which they are found, several of the suggestions in the 'Dawn of Astronomy' seem to be valid when judged in terms of the criteria of this paper. The measurements of the great temple of Amon-Ra at Karnak are sufficiently accurate to establish that this mammoth temple is aligned to the midsummer sunset. His suggestion that this alignment was used as a secret marker to enable the priests to predict the rising of the Nile is an interesting one. The temple of Isis at Denderah seems to be aligned to the rising of Sirius, and the alignment is confirmed by the inscriptions at the temple. The smaller temples at

Karnak could well be aligned to Canopus, the second brightest star in the sky". It is only natural to ask whether Professor Hawkins will be travelling next to Egypt, not to Stonehenge and the Hebrides.

## Finfish Preserved

It is well known that an army marches on its stomach, and it is nearly as well known that the United States Army hopes to fill its stomach with irradiated food. The verbatim record of the review of the United States Food Irradiation programme, held last year by the Joint Congressional Committee on Atomic Energy, shows that of the three agencies charged with fostering what is called the commercialization of food irradiation, the army is the most keen to start work. One army witness spoke of the potential demand of the army for 15 million pounds of irradiated ham a year and 7.4 million pounds of frankfurter sausages, and the same witness pointed out that the difficulty of handling conventionally preserved foods in Vietnam implies that rapid progress with food irradiation would now be particularly opportune. In the event, however, everything will depend on how soon the much discussed Pilot Irradiation Plant is built, and how quickly the Food and Drug Administration can satisfy itself about the safety of irradiated foods so as to be able to approve applications for irradiation licences as a matter of routine. At the hearings there was very little talk of the allegedly toxic effects of the chemical products of irradiating carbohydrates such as have been reported by Professor F. C. Steward and his colleagues (*Nature*, 208, 850; 1965). Dr. Charles L. Dunham did, however, suggest that there are probably similarities between the effects produced by irradiation and the caramelization of sugar. "I have a feeling that we are dealing with the same sort of thing here."

In the long run the most important part of the hearings may be the cost-benefit study which has been carried out by a private organization for the Atomic Energy Commission. The commission had asked for a particular study of a number of perishable commodities, where such advantages as there may be in food irradiation should show up as an actual saving of food which is prevented from decay. The preservation of New England finfish seems to offer the best chance of economic saving, chiefly because there is a growing demand for edible fish in the north-eastern states. The study calculates that a processing plant on the pier at Boston would be able to prevent roughly 5 per cent of the catch from going bad, and that this would be economically attractive because the cost of processing would be less than 2 cents a pound. (The study included a survey among housewives throughout the United States of willingness to buy irradiated foodstuffs, and produced the cheering result that 57 per cent of them would do so.) Unfortunately, irradiation enthusiasts, the only ones who seem to come well out of the cost-benefit study, are papaya, for which it seems that the savings from an increase of shelf-life would be about offset the development of new varieties of most foodstuffs, however, the savings are comparatively great, with fish, for example, and crabs, for example, and in a central

## Science Research Council

THE appointment of Professor B. H. Flowers as Secretary of the Science Research Council, in succession to Sir Harry Melville, has now been confirmed (see *Nature*, 213, 3; 1967). Professor Flowers has been given leave of absence for five years from his post as head of the Physics Department at the University of Manchester. He says that he intends to return to research at the end of his tenure of office. He will remain chairman of the Computer Board.

## Continental Drift

To celebrate its elevation to the status of a university college, Chelsea College of Science and Technology has inaugurated a yearly special lecture, to be called the Chelsea Lecture. The first was given on February 7 by Professor P. M. S. Blackett, on the subject of Continental Drift.

Suspensions about continental drift were not new, said Professor Blackett, but there were now many pieces of evidence which, taken together, made the theory absolutely convincing. The presence of corals, salt and fossils in regions in which they could not possibly have originated all showed a similar trend of movement. Glaciation over large areas of Africa, India, South America and Australia could only have occurred if they had once been much closer together; there was not enough water in the world to make an ice-cap large enough to cover them in their present geographical positions. Rock magnetism had proved a powerful tool, and classic studies of faults such as the Great Glen in Scotland, the San Andreas Fault in California, and the Great New Zealand Fault had shown that relative movement between land masses could and did occur. The rate of movement rarely reached 6 cm/y, and was more usually between 1 and 5 cm/y. More evidence was supplied by the Mid-Atlantic Ridge, placed equidistant between the coasts of Africa and South America. On the ridge itself, there are active volcanoes, but farther out the volcanoes are older, indicating a movement of material away from the centre.

To provide an explanation, Professor Blackett admitted, was harder; convection currents in the Earth's core, and much slower currents in the mantle itself, had been proposed. These could explain why sedimentary rocks, laid down on the ocean floor, were sometimes found on the tops of mountains.

## Compulsion on Pesticides

THE existing voluntary system for controlling the use made of pesticides in Britain will be replaced by a compulsory scheme if the Advisory Committee on Pesticides and Other Toxic Chemicals has its way. In a published *Review of the Present Safety of the Use of Toxic Chemicals in Agriculture* (H.M.S.O., 6s.), the committee points out that the voluntary Pesticides Committee has been found to "work as comprehensive as possible" but "there can be nothing

to prevent a toxic substance being put on the market by a manufacturer not wishing to participate in the voluntary scheme, nothing to restrict the import by potential users of toxic materials, and nothing to ensure that the labels used by manufacturers for marking their materials, on which the effectiveness of the voluntary scheme depends, are as accurate as the considerations of safety would demand. The advisory committee is particularly concerned that the British Government should have powers to act "rapidly and effectively" if the need should arise.

By all accounts, the principal manufacturers of pesticides in Britain now support this conclusion, largely on the grounds that they would prefer to know precisely where they stand. Nevertheless, the introduction of a compulsory scheme would be an important break with the precedents of the recent past. No doubt manufacturers of pharmaceuticals will now be asking themselves whether the existing voluntary arrangements for the approval of drugs under the Dunlop Committee may be replaced by a compulsory system.

On pesticides, the advisory committee recommends that it should be made an offence to sell, supply or import any pesticide product for use in agriculture, gardening or food storage which has not been licensed by the appropriate government department. Pesticides would be tested for mammalian toxicity, carcinogenicity, residue persistence and effects on reproduction and on wild life. It would be for manufacturers applying for a licence to vouch for the safety of their products. The advisory committee considered and rejected the possibility of providing an independent check by government laboratories, largely on the grounds of expense.

## Aflatoxin

DR. J. McL. PHILP of Unilever Research Laboratories at Colworth House has pointed out that a recent item in *Nature* (212, 1512; 1966) may have given a false impression of the toxic properties of aflatoxin. Dr. Philp and his colleagues were among the first to show that aflatoxin, produced by a mould called *Aspergillus flavus* on common foods such as peanuts, maize and rice, was responsible for death in turkeys, and gave rise to liver cancer in rats. It is now known that aflatoxin produces liver damage in many animals, including pigs, cows, rats, monkeys and turkeys. In some cases it has been shown to produce liver cancer, but it is not justifiable to suggest that it produces liver cancer in all those animals for which it produces liver damage. In man, aflatoxin has not so far been implicated either as a source of liver damage or of liver cancer, although the possibility cannot be excluded.

## Zinc for Healing

It appears that zinc deficiency may be very common in human beings. According to the U.S. Department of Agriculture, more than half of the states have zinc deficient soils. Although zinc deficiency has been found widely among domestic animals, there has not so far been much evidence of a specific effect of zinc deficiency in man. An article in the *Lancet* (i, 121;

1967) shows that zinc can accelerate wound healing in human beings when given by mouth. Two groups of healthy young airmen were operated on to drain the pilonal sinus. This operation gives a uniform wound which can be used as a measure of healing capacity. Ten of the subjects were given zinc sulphate by mouth in capsule form three times daily, while ten were not given zinc. The treated airmen showed a marked acceleration of wound healing: their wounds became covered with epithelium and formed no further scab after only 45 days, while the wounds of the control subjects took an average of 80 days to heal. The effect was more marked in the second half of the healing process—the phase of epithelialization. The wounds in the patients given zinc were also cleaner, pinker and healthier than those of the controls.

The obvious question is how zinc acts to make healing quicker. Zinc is known to be concentrated in the skin and epithelia. It takes part in a number of enzyme systems, some of which are likely to play a part in wound healing. Zinc may be incorporated into these systems. One interesting finding in connexion with this piece of research is that the amount of zinc in the urine increases markedly after wounding.

## Preclinical Institute

A new preclinical institute, which will eventually accommodate about 360 students as well as research workers and other staff, was opened on October 31, 1966, at the University of Bergen, Norway. The departments of biochemistry, physiology and anatomy are housed in one block and this is connected to a second block containing the teaching laboratories, auditoria, a museum and a reading room.

In the research block a special feature—unusual in a research institute—is the arrangement of laboratories around a central area which contains special facilities such as service and instrument rooms, and X-ray and tissue culture units, which are thus easily accessible from all laboratories. The biochemistry department has four principal laboratories, each with about eight research workers engaged particularly in projects in molecular biology. Of the five general laboratories in the physiology department one is specially equipped for electrophysiology. Each of the fifteen scientists here has his own office. In the department of anatomy there are laboratories for cytology, histology, embryology, comparative anatomy and dental anatomy. The illustration unit, staffed by an artist and two photographers, is available to all three departments.

## Bacterial Interactions

from a Correspondent in Microbiology

PRACTICAL means of prolonging the steady state of exponential growth of bacteria followed rapidly on the fundamental studies of Monod. Today, continuous flow culture techniques are becoming increasingly important in the study of microbial and cell culture physiology. The use of this technique for investigating population changes within a single bacterial species under the influence of a constant environment has complemented earlier observations from batch cultures, where growth is influenced by a changing set of

conditions. Such studies have clearly demonstrated the interplay of mutation rates and selective processes in the changing character of populations; in particular, the maintenance of exponential growth conditions has revealed the phenomenon of periodic selection. But pure cultures, by definition, are free from the selective pressures of biological competition which operate naturally.

The application of continuous cultures to the study of mixed bacterial populations has posed considerable technological problems, but recent work at the University of Oregon Dental School augurs well for their use in determining interactions between different bacterial species. R. B. Parker (*Biotech. Bioeng.*, **8**, 473; 1966), in an article which contains full details of the mechanical system, describes a two-stage continuous culture unit in which steady state pure populations are fed into a common mixed culture vessel. This equipment has made possible the investigation of interactions between at least six species, and the results of a tri-culture mixture composed of *Staphylococcus aureus*, *Streptococcus salivarius* and *Veillonella alcalescens* are used to illustrate the potentialities of the system. The established conditions of the mixed culture vessel (the "ecostat" condition) are such that the dilution rate,  $D$ , exceeds  $u_{\max}$ , the specific growth rate constant.

The generation times of each species are altered markedly from those characteristic of pure cultures. Thus, *V. alcalescens* and *S. salivarius* show reciprocal stimulation while inhibitory interaction seems to be directed against *S. aureus*. Moreover, under the ecostat conditions, the generation time of *S. salivarius* falls to the remarkably low value of 8.1 ( $s=0.5$ ). Although the residence time of bacteria in the ecostat is short when  $D > u_{\max}$ , this regime assures a steady state and there is no oscillation of population density as a result of interaction. These conditions, however, are far from being natural for mixed populations, and the results of experiments with increased residence times will be of great interest, for under those conditions the experimental system will most closely approach the natural ecosystem. Apart from providing necessary fundamental analyses of microbial interactions, studies of this sort could eventually have important repercussions in experimental pathology and industrial fermentation.

## Ribosomes—Structure and Function

by a Correspondent in Molecular Biology

REMARKABLY little concrete information is available so far about the structure of the ribosome and the part it plays, in physical terms, in the synthesis of polypeptide chains. A systematic attempt to identify which features of the ribosome are essential to its integrity and function has now been made (J. Mol. Biol., **22**, 145; 1966). Heat treatment with formaldehyde results in the loss of the messenger binding site, and the ribosome becomes inactive. Some cross-linking of the ribosome to formaldehyde, the ribosome dissociates into the subunits at high concentrations. The messenger binding site is

after treatment with nitrous acid, which inhibits this function and also causes dissociation of the 70S ribosomes into their 50S and 30S sub-units. Dinitrofluorobenzene is a more specific reagent to distinguish between the aliphatic amino groups of the proteins and the aromatic amino groups of the nucleotides, with which it does not react. With ribosomes there is a slow and limited reaction, indicating that few protein amino groups are accessible. The ribosomes remain integral and fully capable of binding messenger. They will not, however, catalyse the incorporation of amino-acids, and it appears that the specific binding site of transfer RNA is destroyed.

Moore has also examined the effect of perphthalic acid, a reagent which is known to oxidize adenine and cytosine to their N-oxides. This treatment prevents messenger binding and ultimately dissociates the ribosome into its sub-units. Moore concludes that nucleotide amino groups are vital to the association of the ribosomal sub-units, which could involve base pairing, and to the binding of messenger. The latter function, however, is not expected to involve base pairing, since it cannot be supposed that complementary sequences to any given stretch of messenger will usually be available. Indeed, Moore reports that poly-C, pre-treated to saturation with formaldehyde, will bind satisfactorily to the ribosome in competition with poly-U. The nature of any interaction between the bases in the ribosome and sugar or phosphate groups in the messenger remains open to speculation.

Some extraordinary observations on the function of ribosomes are reported by Takeda and Lipmann in the current issue of *Proc. U.S. Nat. Acad. Sci.* (56, 1875; 1966). Active ribosomes from *B. subtilis* have been prepared, but their stability—specifically that of the 30S sub-units—is poor, and the response to poly-U as messenger is relatively low. It is, however, possible to prepare active hybrids with sub-units of *B. subtilis* and *E. coli* ribosomes; 50S *B. subtilis* and 30S *E. coli* sub-units when mixed give good activity, and activity substantially higher than that of homologous *E. coli* ribosomes was achieved when 70S *B. subtilis* ribosomes were mixed with *E. coli* 30S particles. The presence of hybrids was demonstrated by the use of labelled preparations of the latter. It is also of interest that ribosomes from the two species show a distinct preference for interaction with their own sRNA in terms of phenylalanine incorporation.

Another relevant article comes from the laboratory of Marmur (Morrell *et al.*, *J. Mol. Biol.*, 6, 258; 1967). The 5S RNA, which has no transfer function and can be isolated from ribosomes, has recently been provoking much interest and speculation; Morrell *et al.* have isolated this species from *B. subtilis* in a high state of purity, and find that it resembles its analogue from *E. coli* in its properties. DNA hybridization experiments have shown that the 5S RNA is complementary to 2.5-3.0 per cent of the genome, compared with 0.5-1.0 per cent for tRNA. Competition experiments with ribosomal RNA have demonstrated that 5S RNA is a distinct species, and that it is not a tRNA nor a specific fission product of tRNA, which it has so far been considered. The molecule of 5S RNA is a small molecule, but it is yet to be determined whether there is vital,

## Parliament in Britain

In reply to a question in the House of Lords on January 30, the Minister without Portfolio, Lord Shackleton, said that the Atomic Energy Authority, in conjunction with industry, had completed a design study for a combined nuclear electricity generating station and flash distillation desalination plant which could produce 60 million gallons per day of fresh water and 400 megawatts of electricity. The estimated cost of the water from such a plant in Britain, with prevailing interest rates and with the "ground rules" adopted for calculating nuclear costs and allocating plant costs between electricity and the water produced, would be between 4s. 6d. and 6s. per 1,000 gallons, excluding any treatment and delivery charges.

On January 30, the President of the Board of Trade, Mr. D. Jay, and the Parliamentary Secretary, Board of Trade, Lord Walston, announced that the Monopolies Commission had been asked to investigate restrictive practices in the professions which might be contrary to the public interest. The intention was that the Commission should conduct as comprehensive a survey as possible of all professions, omitting from consideration practices which were expressly authorized by Statute or Royal Charter.

In reply to questions in the House of Commons on January 30, the Minister of Public Building and Works, Mr. R. Prentice, said that at the end of 1966 the Directorate-General of Research and Development employed a staff of 231; there were 53 vacancies and the total costs amounted to £1,960,000. The directorate had issued 28 publications besides a monthly statistical bulletin and substantial contributions to the scientific and technical press. Proposals had been accepted for the new Construction Industry Research and Information Association and would shortly be put to the full membership of the Civil Engineering Research Association for ratification. The new association would have a grant from public funds of about £200,000 in its first full year, depending on the amount which the industry subscribed, giving it a budget of about £400,000, of which about three-quarters had already been promised.

In a written answer in the House of Commons on January 31, the Minister of State, Department of Education and Science, Mr. G. Roberts, stated that last year some 15 per cent of overseas students at United Kingdom universities and a few colleges of further education were financed from British official sources. About 22 per cent of university students from developing countries were financed by their own governments or government agencies. Of the 71,000 overseas students in the United Kingdom, some 32,000, including about 24,000 from developing countries, were covered by the Government's decision to increase fees, but no additional cost would fall on those receiving British Government grants or on those who had already embarked on courses supported by the governments of developing countries. Mr. Roberts gave the following figures for United Kingdom students studying in universities in 1964: United States, 1,959; Canada (1963), 687; France, 1,158; Germany, 342; for overseas students studying in the United Kingdom, the corresponding figures are 1,405, 657, 71 and 269; half of these students, however, are attending colleges of further education.

### University News: City University, London

DR. A. F. BROWN, at present reader in natural philosophy in the University of Edinburgh, has been appointed to the second chair of physics as from April 1.

### London

DR. L. HOUGH, at present reader in organic chemistry in the University of Bristol, and chairman of the Carbohydrate Group of the Chemical Society, has been appointed to the chair of chemistry in Queen Elizabeth College in succession to Professor H. Burton. The title of professor of cell biology has been conferred on Dr. E. J. Ambrose and the title of professor of biochemistry of drug action has been conferred on Dr. L. A. Elson, both in respect of their posts at the Institute of Cancer Research: Royal Cancer Hospital.

### Manchester

THE University of Manchester Institute of Science and Technology has created a third chair in chemistry. First holder of the chair will be Professor D. W. J. Cruickshank, at present Joseph Black professor of chemistry at the University of Glasgow. Professor Cruickshank is a theoretical and mathematical chemist, with a particular interest in crystallography and computing, and is treasurer of the International Union of Crystallography.

### Appointments

DR. A. B. ARONS, professor of physics at Amherst College, has been appointed president of the American Association of Physics Teachers, in succession to Dr. M. Phillips, professor of physics in the University of Chicago.

### Announcements

THE Dental Committee of the Medical Research Council has recently been reconstituted under the chairmanship of Professor B. Cohen, head of the Department of Dental Science in the Royal College of Surgeons of England. The other members of the committee are: Professor H. J. J. Blackwood, Sir Robert Bradlaw, Professor A. I. Darling, Professor D. G. Evans, Professor R. L. Hartles, Professor A. D. Hitchin, Professor N. H. Martin, Professor A. E. W. Miles, Professor A. G. Everson Pearse, Professor G. L. Slack and Dr. A. M. Thomson.

A JOINT National Academy of Sciences-National Academy of Engineering advisory committee to the U.S. Department of Commerce's Environmental Science Services Administration (ESSA) has been formed under the chairmanship of Dr. V. E. Suomi, of the University of Wisconsin's Center for Space Science and Engineering. The executive secretary is K. P. Howard, of the National Research Council's Division of Earth Sciences. The committee will review ESSA programmes in sciences, engineering, and services for content and relevance in scientific and engineering quality in relation to the agency's service objectives.

THE Civil Engineering Research Association estimates that its income for 1966 increased by £45,000 to £194,000, and expenditure increased to £234,000. £33,500 of this was of a non-recurring nature, some spent in the association's move to new offices near the Institution of Civil Engineers. The association has now started 87 research projects and has produced a complete set of abstract and keyword cards for all its publications, on the system developed by the American Engineers Joint Council.

THE National Reference Library of Science and Invention has been formed as part of the Department of Printed Books in the British Museum. It will eventually be housed in a new building on the South Bank of the Thames, and is expected to provide fully open access to a stock of 800,000-1,000,000 volumes covering the natural sciences and their associated technologies. At present the library

is being built up in two parts: the Holborn Division, until April 1966 known as the Patent Office Library, and the Bayswater Division.

A BUSINESS meeting of the British Mycological Society will be held in the School of Pharmacy, University of London, on March 31 at 10.30 a.m.

A SHORT course on the "Principles of Power Protection" will be held in the University of Bradford during March 29-31. Further information can be obtained from the Registrar, University of Bradford, Bradford 7.

THE fifteenth annual colloquium on the "Protides of the Biological Fluids" will be held in Bruges during May 3-7. Further information can be obtained from Dr. H. Peeters, Protides of the Biological Fluids Colloquium, P.B. 71, Brugge, Belgium.

THE Institute of Navigation, with the Deutsche Gesellschaft für Ortung und Navigation, the Institut Français de Navigation and the Istituto Italiano di Navigazione, is sponsoring a conference in Paris on April 26, 27 and 28, 1967. The subject of the conference will be "Automation as applied to the Conduct of Craft by Sea and in the Air".

A CONFERENCE on "The X-Ray Analysis of Biological Materials", arranged by the X-Ray Analysis Group of the Institute of Physics and the Physical Society, will be held in the University of Oxford during April 13-14. Further information can be obtained from Dr. E. J. W. Whittaker, Department of Geology and Mineralogy, Parks Road, Oxford.

A CONFERENCE on "Non-Newtonian Flow through Pipes and Passages", sponsored by the British Society of Rheology, is to be held at Shrivenham during September 19-21. Papers are invited for the conference, and a synopsis of not more than 200 words should be sent to Dr. M. F. Culpin, 8 Broadway, Pontypool, Monmouthshire, by May 1.

A ONE-DAY colloquium on "Combustion and Exhaust Problems associated with the Internal Combustion Engine", sponsored by the British Section of the Combustion Institute, will be held at the Thornton Research Centre, Chester, on April 7. Further information can be obtained from Professor W. G. Parker, Department of Chemistry, University of Aston in Birmingham, Birmingham 4.

A SYMPOSIUM on the "Biological Role of Indolealkylamines", sponsored by the U.S. National Institute of Mental Health, will be held at the College of Physicians and Surgeons of Columbia University, New York, from May 10-12. Further information can be obtained from Dr. E. Costa, Department of Pharmacology, College of Physicians and Surgeons of Columbia University, New York 32, N.Y., 10032.

A ONE-DAY meeting, organized by the Mass Spectroscopy Group, will be held in the Geology Department of the University of Manchester on April 5. The meeting will be open to all and will be devoted to the mass spectrometry of inorganic solids including spark source, isotope ratio and Knudsen cell studies. Further information can be obtained from R. M. Elliott, Associated Electrical Industries Ltd., Scientific Apparatus Department, Barton Dock Road, Urmston, Manchester.

A CONFERENCE to review current methods by which scientists can determine the body composition of animals without injuring them, organized by the American Council in co-operation with the National Institute of Agriculture; National Institute of Health, Education and Energy Commission, will be held in St. Louis, Missouri during May. Further information can be obtained from Dr. S. S. Kistner, Department of Biological Sciences, University of Missouri, Columbia Building, Columbia, Missouri.

# Biological Journals and Exchange Groups

In the second half of 1966 there were two important developments affecting the experiment supported by the U.S. National Institutes of Health for the rapid circulation of biological communications within Information Exchange Groups (IEG). For one thing, the National Institutes of Health decided not to continue with the experiment, at least in the form in which it had been established (see *Nature*, 212, 865 and 867). A little earlier, the Commission of Biological Editors had discussed a declaration of policy by a number of biological journals that communications circulated by the IEG would not be accepted for publication (see *Nature*, 212, 4). The statement which follows is the text of that declaration as it has now been agreed within the Commission of Biological Editors.

In the course of a meeting in Vienna on September 10 and 11, we considered some fundamental questions of journal policy in their relation to material that has been distributed by an Information Exchange Group (IEG).

The Commission recognized the value of the Information Exchange Groups as a medium for rapid exchange of informal suggestions, comments, queries, criticisms and general discussion among groups of scientists who share a common interest in a particular field, provided that such memoranda are not intended for publication. This was indeed the primary, original purpose of the IEGs. In order to make this purpose clear the Commission recommended that each IEG memorandum should state on its front page that the memorandum is not intended for publication and is not to be quoted in published papers.

The circulation of an IEG memorandum that is identical (or nearly identical) with a paper simultaneously submitted for publication in a journal can cause much trouble and confusion. The paper may undergo drastic revision before acceptance by the journal; in that case many workers in the field will read the earlier unrevised version, and may fail to read the published paper. The confusion that has arisen in some such cases is unfortunate.

Moreover there are objections to the circulation by an IEG of manuscripts already accepted by journals; that is, the distribution of preprints by an agency entirely independent of the publisher of the scientific paper. This raises questions concerning possible violation of copyright.

## Journal Policies

In view of these considerations the Commission of Editors proposed that its member journals adopt the following policies:

(1) No paper will be considered for publication if that paper, in essentially the same form, has previously been released as an IEG memorandum. Papers may not be submitted simultaneously to a journal and to IEG, nor may papers already accepted for publication in a journal be submitted to an IEG.

(2) IEG memoranda are not to be cited as such in a journal. An author may refer to the information contained in an IEG memorandum as a "personal communication" and the editor may require the author to include the inclusion of reference to the IEG.

(3) IEG memoranda did not advocate the discontinuation of their continuation

as a means of informal communication among scientists with common interests. The policy statement embodied in item (1) is essentially an extension and a restatement of a long-standing policy that has been embraced by nearly all scientific journals; it is designed to prevent multiple publication of the same paper. Editors have operated for some years on the assumption that IEG memoranda were personal communications, not publications. Gradually this distinction has become blurred, since some of the IEGs have distributed many hundreds of copies of papers simultaneously submitted to journals. Such wide distribution of preprints by an agency independent of the publishers of the journals where the papers will appear is in many ways tantamount to publication, and thereby becomes a violation of the rule against simultaneous publication of research results in more than one medium.

## Further Comments

Recently the U.S. Public Health Service has announced, in a letter by Dr. Eugene A. Confrey (*Science*, 154, 843; 1966), that the IEG programme as at present conducted will be terminated early in 1967. In view of this decision, further comments are in order.

All of us recognize that we face a crisis in scientific communication. The volume of the literature has become overwhelming. The need of each scientist to learn promptly of work by others that bears closely on his own problems is increasingly insistent. The IEGs have provided such a means of rapid exchange of information among certain groups of workers with closely related interests; they also provided a forum for controversy and discussion, without the inhibiting influences that would attend formal publication. Scientists moving into new fields of research could make their activities known to others at an early stage, long before publication. All these purposes, and others, can be served by the IEGs, and by similar groups that may arise in future.

By well established practice many scientists circulate advance copies of manuscripts that have been accepted for publication to a limited group of colleagues who share their interests. This practice obviously serves the advancement of science, and no journal regards it as a violation of copyright if the number of copies so circulated is fairly small. Such manuscript copies may fail to reach other workers whose research might profit greatly if copies were available to them. Circulation of very brief notices of current research among members of an IEG

or some similar group might serve to establish communication in cases of this sort.

As editors we recognize the responsibilities of the scientific journals for speeding the process of publication and the distribution of journals after publication. We wish to maintain high standards of careful but prompt reviewing before a paper is accepted; but the interval from acceptance to publication should be as short as possible. Some journals have reduced this interval to two months, sometimes even less, while maintaining high standards of publication; this, of course, requires the co-operation of authors in careful preparation of manuscripts and prompt return of proofs. We recognize the responsibility of the journals to make every effort to shorten publication time.

Distribution of published journals by air can make scientific findings available all over the world within a few days of publication, whereas journals sent by surface mail may take two months or more to reach Asia or Australia from Europe or America. The obstacles to circulation of journals by air are not technical but financial. IEG memoranda, as a result of being sent by air mail, reached investigators throughout the world almost simultaneously; this was one of the great merits of the IEG experiment. The overseas copies of some journals are already distributed by air; the editors of others are eager to follow their example, if they can solve the financial problems involved. We believe that the rather moderate costs of such rapid distribution will be far more than repaid by the resulting stimulus to the progress of science, and the strengthening of communication among the members of the world-wide scientific community. We believe that the International Scientific Unions should play an active part in promoting such rapid communication.

In summary: (A) We recognize the value of the IEGs, and of similar groups that may be expected to arise in future among scientists with related interests, in promoting rapid communication of material not intended for publication. If the scientists themselves wish to form more such experimental groups, and to find ways of meeting the costs of operating them, such groups may well become more numerous and more varied in future. (B) The journals listed below will not consider manuscripts for publication if preprints, of essentially identical content, are to be distributed, in substantial numbers, by an agency independent of the author or of the publisher of the journal. (C) We recognize that editors and publishers of scientific journals must make every effort to accelerate publication and distribution of accepted papers.

The following journals have subscribed to this general statement of policy: *Archives of Biochemistry and Biophysics*, *Biochemistry*, *Biochemical Journal*, *Biochimica et Biophysica Acta*, *Carbohydrate Research*, *Clinica Chimica Acta*, *European Journal of Biochemistry*, *Journal of Biological Chemistry*, *Journal of Clinical Investigation*, *Journal of Lipid Research*, *Journal of Molecular Biology*, *Journal of Nutrition*, *Molecular Pharmacology*.

The following members of the Commission were present at the meeting in Vienna and voted to approve these policies: J. T. Edsall (*J. Biol. Chem.*), J. C. Kendrew (*J. Mol. Biol.*), H. Neurath (*Biochemistry*), E. C. Slater (*Biochim. Biophys. Acta*), W. V. Thorpe (*Biochem. J.*).

## Molecular Messengers

by

E. J. W. BARRINGTON

Department of Zoology,  
University of Nottingham

At the British Association meeting at Nottingham in September 1966, the Zoology section held a symposium on the regulating mechanism of living cells. Most often this seems to depend on the transfer of specific molecules from one place in the cell to another and from one cell to another. The survey which follows is partly based on the discussion at Nottingham.

ONE of the well established sources of evidence for the role of chemical communication in animal organization lies in the field of early development. Spemann's classical concept of the organizer, capable of inducing the overlying ectoderm to differentiate into neural tissue, carried the implication that some form of inducing agent is transmitted from the organizer region to the responding cells. The nature of the substance involved remained obscure, and in the intervening years the exploration of this concept has become an increasingly complicated exercise. For one thing, the action of the primary organizer is a special case of the widespread inductive relationships that operate between the parts of embryos, and which are brought into action at diverse stages of development. Moreover, it is now apparent that the observed phenomena of induction, and the supposed existence of a range of inducing substances or evocators, cannot by themselves provide a complete account of the events of embryonic differentiation.

R. J. Goldacre discussed this problem at the Nottingham symposium. He remarked that one illustration of the inadequacy of the concept of chemical diffusion as a framework of reference for developmental data was that books about it have usually been very thick. This, perhaps, is not necessarily a fault, for it is slim form and facile generalization which are often symptomatic of immaturity in biological research. The thick book is a challenge on which much can be built, but it is one that we understand why it has to be so unwieldy.

### Differences between Cells

A fundamental difficulty in understanding differentiation, as Goldacre expressed it, is that cells are able to respond differently to the same stimulus. They must already be different before they can be different. It is why these differences are so important in molecular genetics, and why they are so important along which the animal develops.

as was outlined by R. A. Cox during this same session. The general trend of thought is sufficiently familiar. Reproduction and development depend on the transcription of the linear sequences of the nucleotides of genes into the linear sequences of the amino-acids of protein molecules. The stored genetic information is supposedly carried from nucleus to cytoplasm by messenger RNA, the latter having had built into it a nucleotide sequence corresponding to that present in the gene. Translation of this sequence into an amino-acid sequence takes place by interaction of the messenger RNA with the ribosomes—the amino-acids being introduced into the reacting system through the mediation of transfer RNA.

### Gene Transcription

Seen from this point of view, cells may be thought of as becoming different during early development because of some form of interference with their transcription systems. Some genes are presumably switched into action at particular stages, while others are caused to become inactive. That many biological agents are able to do this is well known, and Cox gave some examples of this. Actinomycin can inhibit the transcription of the gene; the fidelity with which the messenger RNA is translated is affected by streptomycin; while the tetracycline family of antibiotics appears to inhibit the binding of transfer RNA to the messenger RNA-ribosome complex. Puromycin inhibits protein synthesis by replacing transfer RNA and forming a bond with the growing protein chain, which thus terminates with a puromycin residue. Chloramphenicol appears to act at the stage where an amino-acid is added to the growing chain. Our knowledge of these matters has advanced in a spectacular way, yet—as Cox emphasized—many details of the mechanism of protein biosynthesis are unknown. Moreover, important though it is to know that the transcription of the genes can be controlled, much remains to be learned about the mechanism of this control, and it is just this that is the crucial problem of early development. Each cell in a developing individual seems to have the same complement of identical chromosomes, as was demonstrated, for example, in the well known experiments of Briggs and King. These proved that in the blastula and early gastrula of amphibian embryos the nuclei still retained the full potentialities of the fertilization nucleus. Later the potentialities of individual nuclei become reduced, but this reduction takes place side by side with cell differentiation, and is not the causal factor that determines this differentiation. It would seem rather that differentiation must result when gene transcription becomes switched on or off at particular stages.

### Difficulties about Diffusion

In theory, evocator substances might provide one of the causal factors in the determining of nuclear responses if they could be supposed to operate through diffusion gradients that interact with cells possessing different thresholds. Goldacre argued, however, that such gradient theories must be inadequate. Among the difficulties that they encounter are the fact that, contrary to a widespread belief, diffusion over distances of the order of cell dimensions is very fast; gradients would therefore be difficult to maintain. Moreover, the growth and development of the embryo are executed with great precision; adjacent cells may be sharply differentiated from each other, while tissues become separated by abrupt boundaries. A further difficulty is that the control of biological activities is currently envisaged as being based on negative feedback, and for this the diffusion theory makes no provision at all. If cells had to depend solely on diffusion mechanisms for their regulation they would have no means of telling what other cells were the source of the information that they were receiving. It is difficult to visualize order becoming established in these circumstances; chaos would seem to be the more likely sequel.

Goldacre suggested that a solution to some of these difficulties could be found in the view that the development of a fertilized egg into a multicellular organism is regulated by interaction between the cells of the developing embryo, effected through specific cell-surface connexions. These connexions could make it possible for cell activities to be based on calculations by the cells of what has to be done, and on continuous perception by them of how much has been achieved<sup>1</sup>.

### Cell-to-cell Interaction

Among the illustrations quoted by him in support of this view is the result of dissociating embryos into single cells. The separate cells first move about by amoeboid movement, performing licking movements on one another, and appearing to recognize one another by surface coding factors. As a result they form temporary connexions at first, and then permanent ones later, pulling apart initially if the correct position is not found. Thus the embryo becomes reconstituted, and it can resume normal development once its cells have resumed their correct pattern of contacts. Experiments with models have also been illuminating. Artificial electronic cells have been brought into interaction through appropriate communication channels, and it has been possible to show that the originally identical artefacts may, as a result of such interaction, become different, with a polarity becoming generated in the system.

The concept of the interaction of cells by specific cell-to-cell connexions implies that a transmitting cell can be fed back information from a receiving cell to inform it whether or not the influence that it has transmitted has taken effect. This helps us to understand how it is that fertilized eggs can develop into viable adults despite experimentally devised obstructions that they may meet on the way. When the developing organism consists of only a few cells, it may be possible for more than half of these to be removed without development being fatally impeded. Later, the organism may be able to compensate for extensive limb amputations. This goal-seeking flexibility is like that of a guided missile. Both organism and missile attain their targets because negative feed-back makes it possible for them to compare "what is" with "what ought to be", and then to correct for the difference.

### Cancer Cells

Goldacre concluded by examining the possible bearing of these ideas on the problems of cancer<sup>2</sup>, which appears to involve failures of self-regulation resulting from the breakdown of intercellular communication. Cells in isolation tend to multiply indefinitely as, for example, do mammalian cells in tissue culture, but the growth of cells in the mammalian body is regulated by some form of inhibition. Goldacre found it significant, therefore, that the only regular difference that has so far been demonstrated between tumour cells and corresponding normal cells lies, not in enzyme content or in fine structure, but in the adhesiveness of the cell membrane. Cancer cells, unlike normal cells, do not show inhibition of movement when they make contact with normal cells; instead, they continue to move over them. Moreover, both carcinogenic viruses and chemical carcinogens produce an immediate loss of this contact inhibition when they transform normal cells into malignant ones. These facts suggest that modification of the cell membrane, with consequent interference with cell communication and with the self-regulation of growth, may be an important element in the development of malignancy.

Goldacre was thus concerned in part with factors producing a breakdown in the control of genetic transcription. K. U. Clarke, in a discussion of gene activity in insects, dealt with the problem of avoiding this breakdown. Insects are animals in which development occupies a large proportion of the life span. Thus the decoding of the genetic information that is needed to bring the life

pattern to expression must take place under conditions in which the animal will experience marked fluctuations of food supply, temperature, humidity, and photoperiod. These fluctuations must make it difficult for stability in growth and development to be maintained, and particularly so in small poikilotherms.

### Effect of Environment

Taking as a starting point the pattern of gene transcription already outlined, Clarke classified under three main headings the possible ways in which the environment can modify this transcription during the growth and development of an insect. One possibility is that the overall rate can be speeded up or slowed down. Another possibility is that transcription may be completely stopped, as happens during diapause, when the animal, in response to changes in day length, establishes a state of low energy flow which anticipates the onset of harsh winter conditions. A third possibility is that alternative information can be called forth from the genotype; this happens, for example, in the pupa of the European butterfly *Araschnia levana*, which develops a light colour in cool conditions and a blue colour in warm ones.

As an indication of the mechanisms whereby such changes in transcription may be controlled, Clarke considered the possibility that protein synthesis might be regulated in relation to the intake and utilization of food. In *Locusta migratoria*, swallowing stimulates stretch receptors in the pharyngeal wall, and trains of nerve impulses are conducted from these to the brain. This results in the release of cerebral neurosecretion from the corpus cardiacum and the circulation of this material in the haemolymph<sup>3</sup>. Further, when the animal is intact and is feeding normally, the cells of the midgut are found to show cytological characteristics of active protein synthesis, whereas if the nervous pathways are cut, or food withheld, the appearance of the cells shows that protein synthesis is minimal<sup>4</sup>.

Clarke's argument was that this relationship between protein synthesis and neurosecretory activity, initially demonstrated in *Calliphora*<sup>5</sup> and now found to exist also in *Locusta*, could be a basis for the regulation of growth. But this relationship might itself be influenced in two possible ways. One of these he saw as the control of gene activity by feedback of one of the gene products; this would be acting as a repressor substance, in accordance with the pattern that is now thought to be widespread in animal cells. The other possibility is that the repressor substances can themselves be suppressed by a hormone which, incidentally, would probably be a neurosecretion. The rate of release of such a hormone might be determined by the pattern of activity in the nervous system; a pattern that would itself be determined by the physiological condition of the animal and the environmental stimuli received by it.

### Temperature and Development

Such a system would have consequences that could help us to understand the influence of temperature on the growth and development of insects. We can suppose that the upper thermal limit of the animal is the temperature at which the gene products are being used at a maximum rate, with feedback maximally suppressed. There can be no reserves to provide for the higher rate of protein turnover that would be evoked at still higher temperatures. Above this thermal limit the system must therefore fail and the animal die. Towards the lower thermal limit the use of the gene products will be minimal, so that their repressive feedback action will be maximal. On Clarke's hypothesis this feedback could nevertheless be suppressed by hormone release; some growth and development certainly do occur at low temperatures, the restrictive effects of which are thus to some extent offset.

Clarke pointed out further that study of the biology of related species of insects shows repeatedly that the

main difference between them is thermal tolerance. The system that he was proposing (admittedly to some extent speculative) would allow changes in temperature tolerance to be achieved by relatively few changes in the genotype, leaving most of the genetic information untouched. Genetic adaptation to different climates could thus be readily accomplished, and this is just what is commonly observed in insects.

Goldacre had introduced the theme of molecular messengers as guided missiles. This was taken up again by E. J. W. Barrington in the context of hormonal regulation. He pointed out that the power of hormones to regulate cell activities depended on their capacity to interact in one way or another with the cells that they were regulating, and that this capacity depended not only on their own properties but also on the properties of their target cells, which must be precisely matched with the properties of the hormonal molecules. This is a subtle and flexible relationship, as is well shown in the vertebrates where, despite the complex evolutionary history of these animals, the characteristics of the hormones have remained more uniform than might have been expected. Many of these hormones must have been in existence early in the history of the group, yet the vertebrate endocrine system has always remained available to assist in the establishment of new patterns of adaptive regulation. Some contribution to flexibility of adaptation has doubtless been made by the addition of new hormones during the later history of the vertebrates. An example is progesterone, which regulates pregnancy in mammals. But the main contribution to flexibility has apparently come from the continuous adaptation and re-adaptation of already existing target cells, and from the bringing of new target cells into functional relationship with already existing hormones.

### Thyroid Hormones

He illustrated this argument by reference to the thyroid hormones, which are present throughout the vertebrates, always in the same molecular form. Thyroxine has a growth-promoting action that is demonstrable in fish as well as in mammals, and that is shown in responses of individual parts of the body as well as in total body growth. For example, thyroxine promotes the rate of development of certain dermal bones of the skull in trout alevins if the animals are immersed in thyroxine solution immediately after hatching, while the invagination of the lateral line system is also accelerated.

An extreme example of this kind of effect is seen in amphibian metamorphosis, which depends on the integration of complex morphological, physiological and biochemical changes throughout the body of the larva. This integration is secured by a precisely adjusted relationship between increasing blood titres of thyroid hormones and the capacity of individual cells to respond to them. Metamorphic changes can be induced in frog tadpoles if thyroid hormones are administered to them at an early stage of their life, but these metamorphic changes may be inadequate in extent, and may occur in the wrong sequence, if the cells do not receive the correct amounts of hormone at the correct time. For example, immersion in the wrong concentration of thyroxine may produce a frog without fully developed limbs. If, however, we try to imitate nature more accurately, by gradually increasing the amount of thyroxine that is administered, then we can achieve something that is more like a normal frog<sup>6</sup>.

### Hormones and Enzymes

A particularly striking example of the adaptation of target cells to a hormone is seen in the response of the skin of the tadpole to the local application of thyroxine in a cholesterol-thyroxine pellet. The effect of the hormone on the area of skin overlying the developing fore-limbs is to make it thinner, in preparation for the emergence of the limbs at the climax of metamorphosis. But the area of skin immediately adjacent becomes thicker in

readiness for the assumption of terrestrial life. Two opposite responses are thus given by regions of tissue lying side by side, and superficially indistinguishable. Presumably what thyroxine is doing here and in similar situations is to stimulate or inhibit the production of certain enzyme systems that are involved in growth and maturation<sup>7</sup>. This seems to follow from Tata's finding that the regression of the tadpole tail, which can be evoked by the hormone acting on the isolated tail *in vitro*, is accompanied by increased synthesis of protein<sup>8</sup>. This presumably represents the increased synthesis of certain hydrolytic enzymes that contribute to the regression of the caudal tissues.

### Embryonic Differentiation

This does not, of course, explain what is the basis of the adaptation of the target cells, although it can be assumed in general terms that it depends on the ability of their genetic transcription systems to react in ways that have been determined already in earlier stages of development. We are driven back, in other words, to the problems of embryonic differentiation discussed by Goldacre. He had emphasized the significance of feedback control. Recent findings<sup>6,9</sup> indicate that this plays an important part in metamorphosis, mediated in this instance through the blood stream, and involving both negative and positive feedback.

It is known that early in the life of the amphibian tadpole, before the onset of the visible changes of metamorphosis, the pituitary is able to produce thyrotropin, which can stimulate thyroid activity. At this early stage its stimulating effect is minimal. This is supposedly because its output is kept at a low level as a result of the thyrotropin-secreting cells of the pituitary being highly sensitive to negative feedback from the thyroid gland. However, the neurosecretion of the hypothalamus also enters into the regulating system. This secretion reduces the sensitivity of the thyrotropin-secreting cells to thyroxine, but its effect is at first small because the hypothalamus is only poorly differentiated. According to Etkin's analysis, the effect steadily increases because the thyroxine exerts a positive feedback action on the hypothalamus; the effect of this is to increase its output of neurosecretion, so that there is a progressive increase in desensitization of the thyrotropin-secreting cells. This positive feedback action is by its very nature self-accelerating; thus it rapidly builds up the hypothalamic neurosecretory activity to a point at which large quantities of thyrotropin are released, and the thyroid gland is raised to the high level of activity needed to bring about the metamorphic climax.

### Feedback Systems

It is not clear whether this positive feedback relationship is peculiar to amphibians, or whether the events of metamorphosis are extreme specializations of processes that occur also in other vertebrates. But the principles of organization revealed in amphibian metamorphosis must be widely applicable. This symposium made clear that at all stages of development, and at all levels of complexity, from the single cell to the advanced metazoan, molecular messengers operating through feedback systems are of paramount importance in developmental and physiological regulation.

## BOOK REVIEWS

### OLYMPIANS OF CHEMISTRY

Nobel Lectures in Chemistry 1901-1921

Including Presentation Speeches and Laureates' Biographies. Pp. xii+409. (Amsterdam, London and New York: Elsevier Publishing Company, 1966. Published for the Nobel Foundation.) 160s.

THIS finely produced book commemorates those chemists who gained the Nobel Prize in the first twenty-one years of the present century. Here indeed are riches for the historian of science! Here is pleasant reading for all who would be reminded of the great men whose names frequented the chemistry text-books of old: Nernst, Emil Fischer, Grignard, Haber, the redoubtable van't Hoff and the rest. The lives and scientific work of eighteen men and one woman are recorded. It is interesting to note that no fewer than nine of these were German; four (counting Madame Curie as French) were French; three (counting Rutherford as British) were British; and one each came from the United States, Sweden and Holland. These figures emphasize in a striking way how devoted and imaginative were Germans during the nineteenth century in all branches of chemistry.

The whole book is in English. The chapter devoted to each prizeman is divided into three parts. First there is the translation of the "presentation" speech, given by a Swedish scientist of renown, recounting carefully and concisely the main discoveries in chemistry that the recipient had made. This is in most cases done well and with the minimum of irrelevance. Then comes the prizeman's lecture, in which one of his great pieces of work is recounted at length. Finally there is a short biographical account of the man, giving dates and places, telling what he was like both in the laboratory and at home. Thus for Emil Fischer, who got the prize in 1902, the presentation speech occupies four pages, his lecture on "syntheses in the purine group and sugars" gets fifteen, and the biography four.

The three British prizemen in the book are Ramsay, Rutherford and Soddy. Ramsay's lecture was, of course, on the rare gases of the atmosphere; Rutherford's was on the chemical nature of the alpha particles from radioactive substances, and Soddy's on the origins of the conception of isotopes. It would be presumed on an occasion like a Nobel prize-giving that the recipient would have done his homework well, and certainly with these three, and, indeed, with most of the others too, this is true. Although these lectures are of chemistry in a bygone day, they still make excellent reading. If one was awarding marks one would, I think, give the highest to Soddy, whose fully documented account of the work on the elements he named isotopes, in which he himself took a hand, is a model of scientific exposition. Several of the organic lectures run this one close.

The reader misses one thing: photographs of the prize-winners. The book has a few photographs and diagrams, but it would have been improved if the reader of today might see or see afresh what these Olympians were like. They were great men. They raised chemistry from an almost pre-natal sleep to a healthy and wonderful adolescence. It is meet in a work like this, which tells us so much about them, that we should be reminded of what they looked like. The excellent paper of the book could take photographs directly, thus avoiding the special insertion of photographs required by some books. And, at the price asked for this handsome and carefully edited volume, this request is not churlish. A. S. RUSSELL

## TOP PEOPLE IN PHYSICS

### Nobel Lectures in Physics 1901-1921

Including Presentation Speeches and Laureates' Biographies. Pp. xii + 498. (Amsterdam, London and New York: Elsevier Publishing Company, 1967. Published for the Nobel Foundation.) 160s.

WITH the benefit of hindsight, the wonder is not how well the Nobel Committee chose but that there were so many giants from whom to choose. The innocent reader of this anthology of the Nobel prizewinners in physics between 1901 and 1921 must be forgiven if he asks how the committee could have put a foot wrong. Natural enough to start off with Röntgen (who was unfortunately allowed to collect his medal without delivering the now customary lecture), although even in 1901 it must have been hard to make Lorentz, Zeeman, the Curies and Rayleigh wait until the succeeding three years. To those taught physics in Britain, it is salutary to be reminded that Professor Phillip von Lenard was awarded the Nobel Prize in 1905 for his work on cathode rays, and that the differences of interpretation between him and the school at Cambridge around Thomson were still flourishing when von Lenard came to speak at Stockholm. "We have no evidence that electricity is a special *material* with inertia; it appears to be simply a *state*—a state of the ether . . ." But the following year, in 1906, it was J. J. Thomson's turn to collect a prize and to make a firm declaration of the atomicity of negative electricity. And then, of course, came Lippman (for the development of colour photography), Marconi and Braun, van der Waals, Wien, Gustaf Dalen (who developed automatic regulators for lighthouses and lightships), Kamerlingh Onnes, von Laue, the two Braggs, Barkla (whose influence on the development of atomic theory is much neglected), Planck (rather late in the day, in 1918), Stark, Guillaume (the Swiss who developed the steel alloys of the invar type used widely as stable yardsticks) and finally—also rather late in the day—Einstein in 1921. Plainly the first Nobel committees were more conscious of technology than their successors have been but, even without the claims of the technologists, it is easy to understand why Rutherford had to go among the chemists for his prize.

The style in which the Nobel prizewinners address the Stockholm gathering is revealing. It is a continuing surprise to see how ready the speakers are to deliver a solid professional paper. Perhaps von Lenard explained why when he began saying that "I assume that you would prefer me to tell you what others could not tell you". But some speakers let it slip that they consider the occasion a singular honour, others are pleasantly anecdotal, and the account by van der Waals of how he came to be interested in heat by reading Clausius on the subject is a particularly valuable way of showing how far back go the roots of what is now called physics. The younger Bragg is urbane. Einstein, awarded the prize for "his services to theoretical physics and especially for his discovery of the law of the photo-electric effect", talked unabashed about general relativity and the need for a unified field theory. There are no jokes. But for all their variety, the first two decades of addresses by physics prizewinners must have given the selectors a conviction of their own correctness.

The success with which the Nobel committees made their first choices necessarily prompts the question of whether their task is anything like as easy now that the scale and the pace of scientific work have changed enormously. No doubt a part of the problem is imaginary. History can frequently make people into giants, and giants into demi-gods, and it is necessarily difficult to imagine that each new research student carries the white tie of the Nobel presentation ceremony in his lab coat pocket. But the problem is also partly real. The Nobel system has done well to survive into the sixties without letting scale get the better of it, but the award of the

prizes is bound to seem more and more arbitrary as time goes on. The reputation of an exclusive club depends not merely on the reputation of its members but also on its success in persuading the most eligible people to membership.

JOHN MADDOX

## SERUM PROTEINS

### Serum Proteins in Health and Disease

By Georges Sandor. Translation editor Einhart Kawerau. Pp. xiii + 768. (London: Chapman and Hall, Ltd., 1966.) 252s. net.

THIS is a work on the serum proteins which begins at the beginning. It permits the reader to re-live the extraordinary developments in a field which is now so immense that there are few people left who—like me—can span the history from the past to the present day. As this book demonstrates, much falls into place, and we can understand a subject more deeply if we can follow its evolution. One has to be grateful to the author, who is the Head of the Physical Chemistry Laboratory, Protein Division of the Institut Pasteur in Paris, who has with singular authority assembled this erudite survey.

The book is divided into three parts: (1) The normal serum proteins; (2) their physiology and pathology; and (3) the serum proteins in fluids other than blood. The first part begins with a historical introduction with 342 references, many of them belonging to the nineteenth century. There is a somewhat Victorian flavour attached also to a section on the "euglobulins" which are in fact coprecipitates of  $\alpha$ - and  $\beta$ -globulins in differing proportions. There are chapters on the antibodies (170 references), structure and denaturation of serum proteins (235 references), and a superb chapter on their qualitative and quantitative characteristics, well illustrated and supported by 643 references. The second part of the book is concerned with the origin of antibodies and of the other serum proteins, the role of the reticulo-endothelial system, the major aberrations in  $\gamma$ -globulin synthesis, the lipoproteins, the glycoproteins and the physiological and pathological changes of the serum albumin level. Throughout there is maintained the historical background and the development of the theme up to the present state of knowledge, the support by numerous useful tables, by illustrations, and by copious references. The last part deals with proteinuria, the role of the serum proteins in oedema and effusions, and in the cerebrospinal fluid.

This is an unusual book with a refreshing individuality, and it should be of value to a wide circle of natural scientists and medical men.

H. LEHMANN

## INFRA-RED

### Infra-red Physics

By J. T. Houghton and S. D. Smith. Pp. xiv + 319. (Oxford: Clarendon Press; London: Oxford University Press, 1966.) 60s. net.

IN the several specialized texts on the techniques and theory of infra-red spectroscopy which have appeared in recent years, the emphasis has usually been on the experimental and chemical aspects of the subject, while the physical phenomena associated with infra-red radiation have generally been treated as a part of solid state theory. In this volume, the authors have discarded these somewhat artificial boundaries, and in doing so have succeeded in presenting a unified account of the fundamentals of both the theory and practice of chemical and physical infra-red spectroscopy in the spectral range from 0.8 $\mu$  to 1,000 $\mu$ .

The volume begins with a brief account of the basic principles of the classical and semi-classical treatments of

the interaction of radiation with matter to provide the necessary background for the discussion in the succeeding chapters. This is followed by an account of the infra-red spectra of molecules, for which the reader would find it useful to have read *Introduction to Quantum Mechanics* by Pauling and Wilson. The authors have written an excellent comprehensive description of the optical properties of semi-conductors which is illustrated with well chosen data and diagrams. The theory of the optical properties of metals has been making great progress in recent years, which can be seen, for example, from *Proceedings of the International Colloquium on the Optical Properties of Metals and Alloys*, Paris, 1965, much of which is due to the application of the theory developed for semi-conductors. It is therefore a pity that metals have been specifically omitted from the discussion. Dare we hope that, for the next edition, the authors will be persuaded to extend their account to include metals?

The rest of the book is concerned with experimental techniques and applications; a description of infra-red detectors is followed by a clearly presented discussion of the various dispersive systems available, which is remarkable for the wealth of useful information contained in so few pages. In contrast, the section on interference filters confuses the reader by compressing too much information into too few pages. The difficulties of applying conventional microwave techniques to the far infra-red spectral region (50–1,000 $\mu$ ) are well illustrated, though perhaps too much space is devoted to these methods at the expense of the grating and interferometer techniques that are producing results.

In general the book is well presented, with clear diagrams and a useful quantity of data. There is a good selection of references.

The book provides a link between the elementary undergraduate texts and the more specialized texts on molecular and solid state theory of infra-red spectroscopy. It should therefore be useful to final year students, and have a strong appeal to research workers to whom it is highly recommended.

R. W. G. CLARKE

## SANDWASPS OBSERVED

*Comparative Ethology and Evolution of the Sandwasps*  
By Howard E. Evans. Pp. xvi + 526. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1966.) 120s. net.

THIS book is probably the most detailed comparative behavioural study of a large group of wasps that has ever been published, and it is written, moreover, by a worker who has made a very large number of personal observations. The insects studied are not all the sandwasps (Sphecidae) but one large subfamily, the Nyssoninae, the members of which nearly all nest in sand and constitute a fairly compact group of about 1,000 species with a considerable range in structure and habits. They include the genus *Bembix*, which has long been famous for its elaborate nesting behaviour and which is now made even more interesting because a comparative study of many species (more than a dozen in the western United States) shows how some of the more specialized features such as day to day provisioning of the larvae could have been evolved. As the author remarks (p. 495), it is difficult to reach any certainty about the evolution of instinctive behaviour. It is certain, however, that it is easier and more profitable to speculate about a wide range of species of somewhat different habits and living in different habitats than it was for such early workers as J. H. Fabre, who were not usually familiar with more than one or two species in each genus.

It is clear that even in this long book the author could not have made a detailed survey of structure as well as

of habits, and indeed structure is not neglected. There is a considerable section devoted to the classification of the genera and to their fossil history in Chapter 13. Yet I feel myself that more work of the conventional type on the comparative morphology of the group would have been justified. In *Bembix*, for example, where there is such an interesting range of specific behaviour, very little attempt has been made to group the apparently rather uniform wasps within the genus. The unexpected correlations between structure and behaviour which are often discovered in this way appear to supply the best though far from conclusive test for any phylogenetic speculation. The very few identified fossils at least have the value of proving that insects like modern Gorytine (relatively unspecialized members of the group) occurred in the Eocene and Miocene. It is difficult to overestimate the support that such fragmentary facts lend to a conventional classification.

Apart from the comparative and evolutionary study of behaviour, the work is also a mine of facts. The habitats, nests, oviposition type, cocoons, prey and parasites of a great many species are listed and often illustrated by excellent photographs or by drawings. Although the American fauna forms the backbone of the study, observations from all over the world are brought together and a large literature is summarized. Moreover, to many entomologists the work will also be a revelation of how a study of comparative ethology should be made on a group which is eminently suitable for the attempt. It is not always easy to find nesting sandwasps, and even when found they demand prolonged observation under daunting climatic conditions. Dr. Evans has been studying them for ten years, but it is a matter for admiration how much he has done, how clearly he has described it, and to what interesting though well supported theories he has been led.

O. W. RICHARDS

## MICE IN LABORATORIES

*Biology of the Laboratory Mouse*

Edited by Earl L. Green. Second edition. Pp. 700 + 3 plates. (New York: McGraw-Hill Book Company, Inc.; Maidenhead: McGraw-Hill Publishing Company, Ltd., 1967.) \$16.50.

THE mouse is by far the most important laboratory mammal, not least because the existence of many inbred and genetically homogeneous strains provides a unique basis for quantitative studies in virtually every field of biology and medicine. The first edition of the *Biology of the Laboratory Mouse* was published in 1941 under the editorship of G. D. Snell. After the lapse of a quarter of a century, we now have the long awaited second edition. Its editor is Dr. Earl L. Green, the director of the Jackson Laboratory at Bar Harbor, Maine, U.S.A., and the successor to Dr. C. C. Little, who founded that famous institution. The team of thirty-one contributors to this volume includes some of the foremost authorities in their respective fields. The scope of the work is indicated by the chapter headings: the laboratory mouse; breeding systems; keeping records; husbandry; nutrition; nomenclature; nuclear cytology; mutant genes and linkages; multiple factor inheritance; radiation genetics; reproduction; early embryology; anatomy; teratogenesis; genes and development; physiological characteristics; blood and blood formation; blood coagulation; inherited metabolic variations; endocrine variations; pigmentation; acute responses to ionizing radiation; responses to drugs; genetics of tissue transplantation; cell, tissue and organ culture; lifespan and ageing patterns; characteristic tumours; transplanted tumours; constitutional diseases; infectious diseases; immune functions; neural, sensory and motor functions; and patterns of behaviour. There is also a useful bibliography of techniques. In

general, the contributions are authoritative and well written, and each is followed by an extensive list of references. The book is well illustrated and excellently produced, and there is a good index of 43 pages. Quite apart from genetical libraries, for which this book is, of course, an absolute essential, it is difficult to see what biological or medical laboratory could afford to be without a copy. As a work of reference, it is clearly invaluable, and at least one person not unfamiliar with the mouse has made several interesting discoveries in thumbing through this volume.

H. GRÜNEBERG

## CONNECTIVE TISSUE ENDOCRINOLOGY

### Hormones and Connective Tissue

Edited by Gustav Asboe-Hansen. (Scandinavian University Books.) Pp. 431. (Copenhagen: Ejnar Munksgaard, 1966.) 103 D.kr.

DR. ASBOE-HANSEN is at the centre of a team of physicians, surgeons, anatomists and dermatologists who join together in a unique experiment in collaborative research on connective tissue metabolism. In 1954 he edited a group of papers *Connective Tissue in Health and Disease* which introduced the work of the group, but which by the inclusion of reviews by other experts provided a volume holding within its covers all the growing points of a rapidly expanding subject. During the intervening thirteen years, connective tissue studies have advanced quickly, and Dr. Asboe-Hansen's present volume demonstrates not only the quantitative development in Copenhagen but also the change in emphasis there. The broad coverage of the earlier volume has been replaced by the treatment in depth of a single aspect.

The seventeen chapters cover a variety of aspects of connective tissue endocrinology. The first two deal with the effects of a broad spectrum of hormones on tissue mucopolysaccharides and on the formed elements of blood. Another seven chapters deal with the specific effects of individual hormones on selected tissues, whereas a further group is concerned with more clinical aspects of connective tissue metabolism.

During the past decade, considerable evidence has been provided from which the primary and secondary structure of the collagen fibre has been deduced. It might appear surprising, therefore, that a book of this calibre fails to include any correlation between chemical structure and function and a discussion as to show this is determined by environmental and especially by hormonal influences.

Unfortunately metabolic studies on connective tissue components have not kept pace with structural studies, and research in the first of these fields is still very much at the observational level. Many of the contributions to the present book, therefore, consist of experimental observations which appear to have little relationship with one another. Such a compilation does not lend itself to easy reading. It is not a book to be read at bed-time, but the solid meat between its covers should be a useful source of information for those wishing to learn how individual hormones may affect the tissues in which they are interested.

If one has to make any criticism of the subject matter of the book, it has one fault in common with any publication originating in a single institute or group of workers. Because of the circumscribed nature of the work undertaken by the various collaborators, their approach is uniform. A large proportion of the references quoted are Scandinavian and the work of one or two other schools engaged in similar studies is virtually ignored. If, however, the volume is accepted for what it is—a survey of the work of a highly active and energetic research group in relation to selected studies elsewhere—

it should prove to be of great use to other workers in the field.

As is usual with volumes from Munksgaard, the book is well produced. It might, however, have benefited from an author index.

D. A. HALL

### Problems in Mathematical Physics

By N. N. Lebedev, I. P. Skal'skaya and Ya. S. Uflyand. Translated by A. R. M. Robson. Translation edited by J. Reinfelds. (International Series of Monographs in Pure and Applied Mathematics, Vol. 84.) Pp. viii+406. (London and New York: Pergamon Press, Ltd., 1966.) 63s. net.

THIS book consists of a collection of problems on the differential equations arising in the mechanics of continuous media, in the vibrations of mechanical systems, in the theory of heat conduction and in magnetism and electricity. It includes problems on the use of curvilinear co-ordinates, Green's functions, conformal transformations, eigenfunction expansions and integral transforms. There is a short chapter on integral equations. Solutions to about one in seven of the problems are given. There are also hints for the solution of some of the others, and each problem has its answer printed immediately below it. At the beginning of each section there is a brief introduction to the general method involved in the following problems.

The easier parts of the book are of a standard appropriate to a first-year undergraduate course in applied mathematics or physics at a British university, but some of the problems reach a degree of complexity unlikely to be encountered in first degree work. The solutions provided are of adequate clarity, but the translation is very often clumsy and sometimes obscure.

It is difficult to see who will use the book. It cannot be used as a text-book; the introductory sections are too brief, and the number of solutions too small for this. Many of the existing text-books in this field already have adequate selections of problems. No doubt hard-pressed examiners will turn to it from time to time.

The book is well produced, and the price is reasonable.

W. E. PARRY

### Modern Methods of Chemical Analysis

By J. A. Barnard and R. Chayen. Pp. xiii+273. (Maidenhead and New York: McGraw-Hill Publishing Company, Ltd., 1965.) 42s. 6d.

THIS book is primarily for student readership and the subject matter derives from a second year course for chemical engineering undergraduates. There are six chapters—Volumetric Methods, Polarography, Spectroscopic Analysis, Mass Spectrometry, Radiochemical Methods, and Separation Techniques. Included in the text are 56 detailed experiments covering all the chapters with the exception of mass spectrometry. In their preface the authors state that the book will persuade the reader that "...many of the skills needed can be fairly quickly acquired, and the basic theory readily understood". On the experimental side the claim is fully substantiated; the exercises are carefully chosen to illustrate the facets of the techniques described and they are within the scope of a reasonably well equipped college laboratory. This part of the work can be recommended with confidence.

In general the basic principles are less well presented. One would like to have seen rather more emphasis on the scope and limitations of the techniques described to give the reader a true perspective of the factual material. The balance of theoretical material is occasionally uneven; in discussing ion exchange, for example, several pages are devoted to the synthesis of organic resins, but no mention is made of the experimentally important selectivity of the resins for ions of varying charge and size.

Nevertheless the book has much to commend it. The presentation is excellent and the text is carefully pitched at student level throughout. Provided the reader accepts that additional theoretical material from other sources is essential to support its undoubted practical value it will serve as a most useful handbook. The standard of production is good and the book is reasonably priced.

J. K. FOREMAN

### A Dictionary of the Flowering Plants and Ferns

By J. C. Willis. Seventh edition, revised by H. K. Airy Shaw. Pp. xxii+1,214+liii. (London: Cambridge University Press, 1966.) 100s. net; \$18.50.

IN the seventh edition of "Willis" perhaps the original aim of its author is not quite fulfilled. Dr. Willis said, in his original preface, "I have endeavoured to bring together in this book as much information as is required by all but specialists, upon all plants generally met with, and upon all these points—morphology, classification, natural history, economic botany etc.—which do not require the use of a microscope . . .". The great increase in botanical knowledge in the last seventy years has required that some of the information previously included in the dictionary be omitted if the compact, single volume format is to be preserved. This "Willis", therefore, in its 40,000 entries gives only generic and family names; common names have gone, and so have the horticultural notes—possibly a loss to some non-specialists, but such topics are treated in full in other easily accessible works. The information which is given in this largest-ever edition is as full as it could be; the aim has been to include every generic name from 1753, and every published family name from 1789. Some suprafamilial and infrafamilial taxa have been included if they are not based on generic and family names, and alternative generic names and variant spellings have been supplied in many cases where these exist. All this must greatly increase the value of the book to students and others who use it as a reference work of taxonomy.

MARY LINDLEY

### Tables of Physical and Chemical Constants, and Some Mathematical Functions

By T. H. Laby and G. W. C. Kaye. Thirteenth edition. Pp. 249. (London: Longmans, Green and Co., Ltd., 1966.) 35s. net.

PREPARING comprehensive tables of physical and chemical data is a thankless task. The authors must jettison opinions, enthusiasms and prejudices in the pursuit of accuracy; no sooner have they finished one edition than they must start work on the next, like intellectual painters of the Forth Bridge. Kaye and Laby, who fathered the first edition of this book in 1911, had at least the satisfaction of being immortalized by it, but the present editorial board soldier on in comparative anonymity. They are Professor N. Feather, Dr. H. Barrell, Dr. E. A. Coulson and Mr. J. M. C. Scott, and they have produced the thirteenth edition with the help of a large band of contributors.

There has been a seven year gap since the last edition, a long time, as Professor Feather observes, in relation to the growth of knowledge in science. There are five additional tables, covering critical constants and second virial coefficients of gases, bond lengths, energies and angles, force constants, stability constants, and solubility products. The format remains the same; each entry includes a brief résumé containing references, which are invaluable because a book this short could scarcely hope to include everything, and references to further sources of information are certainly needed. The fact that the book has not been allowed to expand unchecked is a considerable editorial triumph, and although the growth of science probably means that it is less comprehensive than it was in 1911, it is no less indispensable. NIGEL HAWKES

## OBITUARIES

### Dr. Alick Isaacs

THE death on January 26, 1967, at the age of 46 of Dr. Alick Isaacs, has robbed this country and the Medical Research Council in particular of a leading virologist with an international reputation. After a brilliant undergraduate career in Glasgow where he was born, Isaacs graduated in 1944 and spent the next three years as McCunn research scholar in the University Department of Bacteriology. He then sought training in virology, and spent first a year in Sheffield in the Department of Medicine and then two years at the Walter and Eliza Hall Institute for Medical Research, Melbourne. Two subjects attracted his interest as early as 1948—virus variation and virus interference, and it was the pursuit of the latter phenomenon which brought him stimulus, achievement and reputation to the end of his life.

First, however, variation of different cultural lines of influenza virus drew Isaacs's interest. In Melbourne he studied it as a genetic phenomenon, utilizing the technique of passage at limiting dilution to isolate pure clones of virus. This experimental work stood him in good stead when he returned to London to direct the World Influenza Centre at the National Institute for Medical Research in 1950. There strains of influenza viruses from all over the world were studied serologically and identified by this and other methods. Isaacs used the antigenic variation of the influenza viruses to pin-point the spread of epidemics and thus to throw light on the transmission of the infection. His subsequent interest in attenuation of influenza strains for possible use in immunization was hampered by his absorption in the subject of virus interference.

This had interested him particularly in Australia, and he continued work on the phenomenon with increasing tempo. Then in 1957, together with Lindermann (a Swiss virologist), he reported the evidence that the phenomenon was a result of the elaboration by the animal cell of a protein with broad antiviral properties named by him "interferon". In the next five years, Isaacs and a series of visiting collaborators at the National Institute studied interferon, its production, mechanism of action and chemical and physical properties. He showed its biological purpose in aiding recovery from virus infection, its potential use as an antiviral prophylactic, and its experimental value as a model for research on antiviral substances. That it never became a practical weapon in the prevention or treatment of virus infections was a disappointment which in no way clouded the scientific importance of his discovery.

Isaacs succeeded Sir Christopher Andrewes in 1961 as head of the Virology Division at the National Institute, but later his health, already precarious, showed the need to conserve his energy. He became head of the Laboratory for Research on Interferon where he had fewer distractions.

In 1962 he received an honorary M.D. at the Catholic University of Louvain, and in 1966 he was elected F.R.S. To many who visited the Institute or worked in collaboration, Isaacs showed a warmth of friendship which was surprising in one so shy in youth. He retained his puckish wit and enjoyment of life to the end, and in this he was aided by his wife, Dr. Susannah Gordon—whom he met in Sheffield. His loss from a second subarachnoid haemorrhage has left a vacant corner in the lives and memories of many who knew Isaacs and admired the simplicity and integrity of all that he undertook.

C. H. STUART-HARRIS

### Dr. T. A. Munro

THOMAS ARTHUR MUNRO died on December 18, 1966, at the age of 61. He had been medical superintendent of the Royal Edinburgh Hospital since 1954. At that time many developments were taking place, and Munro delighted in them, for he was a shrewd and practical man who made constant improvements in the general amenities of the hospital. His post was a demanding one, but he found time for clinical as well as administrative work.

Munro was educated at Edinburgh Academy and the University of Edinburgh, where he graduated M.B., Ch.B. in 1928. He was a resident in the Edinburgh Royal Infirmary and then joined the staff of Sir David Henderson in the Royal Edinburgh Hospital, Morningside. He was awarded a Beit fellowship and went to work with Professor Meyer in Baltimore and with Professor Macfie Campbell in Cambridge, Massachusetts. He returned to England and to a research post with Dr. Turner at the Royal Eastern Counties Institution and here his ability for research was revealed. Working with a large body of clinical material he investigated genetic and biochemical factors in the aetiology of what, for simplicity, can be called mental defect. Finally he was able to clarify the condition of oligophrenic phenylketonuria and its avoidability. This hopeful approach has continued to develop.

When the Second World War began he joined the Emergency Medical Service and later the R.A.M.C., where he became a colonel A.M.S. At the end of the war he was offered the position of chief of the Psychiatric Services in Guy's Hospital. This post was an arduous one; there was much administrative, teaching and clinical work; he had the interesting but difficult task of integrating the work of the Psychiatric Department with that of the hospital generally. A certain amount of private clinical work was inescapable, but he approached it all with enthusiasm until in 1954 he returned to be chief of the hospital in which his career had begun. In 1965 he saw a new department, the Andrew Duncan Clinic, opened.

Munro was a man with a strong sense of humour and he was a good public speaker. He was still, in the sixties, being visited by American friends he had first met thirty years earlier. He was extremely social and it is a happy recollection that one of the last gatherings he organized was to celebrate the eightieth birthday of Sir David Henderson, from whom Munro gained much of the knowledge and experience which he used to the benefit of psychiatry.

W. M. H.

### Professor G. P. Crowden

PROFESSOR G. P. CROWDEN, emeritus professor of applied physiology of the University of London, died at Edgware on November 22, 1966.

He was born in 1894, and had a distinguished academic career at the University of London, graduating B.Sc. with first class honours in physiology in 1921, M.Sc. in 1926, M.R.C.S., L.R.C.P. in 1929, D.Sc. in 1937 and in the same year he was elected M.R.C.P., London. He was appointed lecturer in physiology at University College in 1927 and at the London School of Hygiene in 1929, where he served successively as reader in industrial physiology and professor of applied physiology until his retirement in 1962. He was awarded the O.B.E. in 1944.

Crowden served with the British Expeditionary Force from 1915 to 1918, first as intelligence officer and later for special duties with a gas brigade. He maintained his connexion with the armed forces through the Territorial Army and the O.T.C. medical unit, and served during the Second World War as colonel, R.A.M.C., in London and West Africa. Since then he has been consultant in

applied physiology to the army and a member of the Army Personnel Research Committee.

In 1927 Crowden had spent a year at Harvard School of Public Health and early in his career he saw the need to apply the principles of engineering, physics and chemistry to the solution of problems of preventive medicine. His teaching and research covered an astonishingly wide range of subjects within the field of applied physiology and occupational health. He was a practising ergonomist many years before this word had been coined. Man's physiological environment and the reactions of man as a whole rather than of individual organs were his interests. Although his main research was in the field of muscular work, nutrition, noise and deafness, his interests ranged from comfort in living quarters in ships in tropical heat to insulation against cold in Antarctica. He published work on physiological problems of housing, protective clothing, artificial respiration and pneumatic drills. He did much to popularize the use of aluminium foil for reflecting radiant heat in solar topees and other headgear, fire-fighting suits and insulation of buildings.

He was a lucid and effective teacher, concentrating on the principles of the common ground between the relevant disciplines. Whether he was lecturing to the main classes of medical graduates or nurses or students of tropical architecture he emphasized the need to look for and, as far as possible, rectify any departure from optimum conditions of man at work or in the home. He was a strong advocate of the value of practical work, striving wherever possible to provide individual student participation; for example, every student had an opportunity to measure his own hearing by gramophone audiometer and to assess the components of the thermal environment, summarizing their overall effect on man by the effective temperature scale. There were many demonstrations in the evaluation of lighting, noise, radiant heat, muscular work, ventilation and protective clothing.

I shall long remember the applause from members of the Physiological Society after a communication given by Crowden at a meeting at the National Hospital, Queen Square. The subject was the superiority of nylon as compared with cotton mosquito nets with respect to permeability to air movement and to light. The spontaneous ovation showed that the audience as a whole appreciated the clear exposition of an important practical point, but it also owed much to their esteem and affection for the speaker.

M. L. THOMSON

### A. J. Berry

ARTHUR JOHN BERRY, senior fellow emeritus of Downing College, Cambridge, and formerly university lecturer in chemistry, died on January 15, at the age of 81.

He graduated from the University of Glasgow and then went to Cambridge, where he took his Natural Sciences Tripos. He started to teach chemistry in 1911, and this remained one of his great interests; he became director of studies in chemistry and physics at Downing College soon after his election as fellow in 1913, and continued in this post until his retirement in 1951. For many years Berry had great influence on the teaching of chemistry in Cambridge. His early research interests were in analytical chemistry; he was the author of several books on the subject and on the chemistry of the atmosphere. In his later years he was increasingly concerned with the history of science. Berry wrote a number of useful books on the history of chemistry, including a biography of Cavendish, which was notable for a particularly clear style and the obvious affection of the author for his subject. Although Berry made no original contribution his books will continue to be valuable as introductions for students for a long time.

Berry had served as vice-master of his college and as a senior proctor.

Fig. 1. Amino-acid sequence of ribonuclease<sup>1</sup>.

## X-ray Investigation

This section deals with X-ray data collected since 1964, using the linear X-ray diffractometer<sup>9</sup>. The unit cell dimensions for monoclinic ribonuclease grown from 50 per cent aqueous alcohol are  $a = 30.31 \text{ \AA}$ ,  $b = 38.26 \text{ \AA}$ ,  $c = 52.91 \text{ \AA}$ ,  $\beta = 105^\circ 55'$ , with space group  $P2_1$  and two molecules per unit cell. These crystals correspond to ribonuclease II described by King *et al.*<sup>7</sup>. The X-ray molecular weight measured by Carlisle and Scouloudi<sup>8</sup> is reported as 13,400 and as determined from the amino-acid sequence is 13,683. The phases of the X-ray reflexions from spacings greater than  $5.5 \text{ \AA}$  have been determined by the method of multiple isomorphous replacement which has been used so successfully in the study of myoglobin<sup>9,10</sup>, haemoglobin<sup>11-13</sup>, lysozyme<sup>14</sup> and carboxypeptidase A (ref. 15). Table 1 shows a list of heavy atom derivatives prepared and used in the course of this work.

Table 1

No.	Derivative	Method of preparation
(1)	RNase + sodium <i>p</i> -hydroxy-mercuribenzenesulphonate	Co-crystallized
(2)*	RNase + potassium hexachloroiridate	RNase crystals soaked for 6 months
(3)	RNase + potassium hexachloroiridate	RNase crystals soaked for 6 weeks
(4)	RNase + 2'-cytidylic acid + potassium uranyl pentafluoride	RNase crystallized with nucleotide and then soaked for 6 weeks
(5)	RNase + potassium uranyl pentafluoride	RNase crystals soaked for 6 weeks
(6)*	Homocysteinyl-RNase (2) + sodium <i>p</i> -hydroxymercuribenzoate	Ribonuclease chemically modified and then reacted with sodium <i>p</i> -hydroxymercuribenzoate
(7)	Homocysteinyl-RNase (1) + sodium <i>p</i> -hydroxymercuribenzoate	

\* This derivative was not used in the final phasing of the X-ray reflexions.

One of the difficulties in this work, and which also occurred in an earlier study of ribonuclease<sup>18,22</sup>, has been the appearance of multiple heavy atom sites in metal substituted crystals. With the exception of the chemically modified ribonucleases, numbers 6 and 7 of Table 1, where there is only one heavy atom site for each protein molecule as shown by Patterson difference maps (see Figs. 2a and 2b), all the other substituted crystals yield multiple occupancy whether or not the substitution has been carried out by co-crystallization or diffusion methods. The aim, therefore, was to use those substituted crystals with the least number of effective sites in any substitution and to neglect those sites where occupancy fell below about 10 per cent for the heavy metal concerned. Column 5, Table 2, shows the effective site occupancy for those heavy atom derivatives used in the final phasing of the X-ray reflexions.

The positions of the heavy atoms, in each of the derivatives, were found independently from Patterson difference maps and refined by Rossmann's method<sup>18</sup>. The positions of heavy atoms from different derivatives were then brought to a common origin through Fourier difference maps using approximate phases for the reflexions from the parent protein crystals. In this way, from single isomorphous methods, the phasing of the X-ray reflexions was extended to double isomorphous methods, taking the derivatives in pairs, and then to triple

Fig. 2. Section at  $V = 0.5$  of Patterson difference of (a) Hg-homocysteinyl-RNase (1) and (b) Hg-homocysteinyl-RNase (2).

Fig. 3. Histogram showing the agreement between the phases calculated from derivatives 1, 3, 4 and 5, 6, 7.

isomorphous methods. The phase determining procedures used here were those based on the phase probability method described by Cullis *et al.*<sup>12</sup>.

In this way the atomic positions were cross-checked and finally two independent sets of triple isomorphous phases were obtained. The histogram (Fig. 3) shows the number of reflexions plotted against  $20^\circ$  ranges of  $\Delta\phi$ , the phase angle difference between the two sets of data. All the reflexions from spacings greater than  $5.5 \text{ \AA}$  have been used in plotting this curve and one encouraging feature not revealed by it is that nearly all the reflexions with  $\Delta\phi$  greater than  $90^\circ$  either have a low figure of merit in one or other set of data or else have a small protein structure amplitude. The average difference in phase angle as calculated between the two sets of derivatives for reflexions with "figures of merit" greater than 0.7 was  $40^\circ$ . As these independent sets of phases involved more than 60 per cent of the reflexions in the  $5.5 \text{ \AA}$  region, we had some confidence in bringing the two sets together for the final phasing. Here about 80 per cent of the reflexions had figures of merit greater than 0.7.

For the final phasing, however, five derivatives (see Table 2) were used and the refinement of the heavy atom parameters was carried out by a programme written by R. E. Dickerson, R. A. Palmer, D. M. Blow and D. F. Koenig, based on the method described by Dickerson *et al.*<sup>17</sup> in their study of myoglobin. Throughout the work, electron density maps were calculated at intervals  $a/30$ ,  $b/20$ ,  $c/30$  of the unit cell sides and for the final synthesis 389 reflexions were used, using slightly sharpened coefficients with  $\phi$  best phases.

Table 2. HEAVY ATOM PARAMETERS

	$x$	$y$	$z$	$B$	$N$	$E$	$R\%$
(1) Sodium <i>p</i> -chloro-mercuribenzenesulphonate	0.957 0.317 0.922 0.188	0.448 0.472 0.031 0.090	0.950 0.542 0.948 0.089	77.8 61.4 80.1 48.3	39.7 31.5 8.4 21.8	24.1	11.0

$B$ , Isotropic temperature factor;  $N$ , occupancy of heavy atom sites in electrons;  $E$ , root mean square "lack of closure" error averaged over all reflexions;  $R$ ,  $\frac{\sum |F_{\text{calc}} - D|}{\sum |F_{\text{calc}}|}$  where  $D$  is the third side of the

phase triangle and  $D$  is calculated for the most probable phase angle.

Fig. 4a, b, and c. Photographs of the electron density map of ribonuclease shown in overlapping groups of sections.

As a check that the positions of the heavy atoms of the different derivatives had been correctly determined and that the correct origins had been found, electron density maps were calculated using phases determined by taking the derivatives singly, then combined in pairs and finally in threes. It would be expected that the phases used in each of these calculations were not necessarily as reliable as those where all derivatives were used together. In none of these syntheses was it possible to use all the terms within the 5.5 Å limit and also no two syntheses necessarily contained the same terms. Naturally, such maps must show variations within themselves, but a close scrutiny revealed many consistent features between all of them which gave an indication of what to expect, and to look for, in the final electron density map calculated using phases determined from the five derivatives taken together.

### Electron Density Distribution

Figs. 4a, b and c show sections parallel to (010) of the electron density of the asymmetric unit  $a \times b \times \frac{1}{2}c$  set out on 'Perspex' sheets. For clarity of presentation, the sheets have been photographed in three separate overlapping groups. A noticeable feature is a crude ring of density distributed about a lighter region, and photograph Fig. 1b has been taken in such a way as to emphasize this aspect. It will be shown later that the four cysteine residues of the molecule are to be found in this ring. The axis of this ring of density lies approximately perpendicular to (304), which set of planes give rise to one of the strongest reflexions from the crystal. This particular feature of the electron density distribution was also found in an earlier study of the crystals, using photographic data<sup>18</sup>. Fig. 5 shows the packing of the molecules on (010).

In this respect it is interesting to look at the distribution of the heavy atom sites in the unit cell. Figs. 6a and b show these sites plotted on (010) and (100), respectively. There is a tendency for many of the heavy atoms, especially those with reasonably well occupied sites, to cluster in a region parallel to the  $b$  axis at  $x=0, z=0$ , where the two molecules are well separated from one another. Another noticeable feature is that this cluster of atoms lies near to the active site of the molecule, but it is

clearly not possible to comment on the significance of this feature at this stage of the work.

Fig. 7a shows a photograph of a wooden model of the density distribution. The dashed line indicates a cleft in the molecule in which lie inhibitors such as 2'-cytidylic acid, and the homocysteinyl residue which is probably attached to lysine 41 (see Figs. 7b and c).

### Active Region of the Molecule

Chemically it is known that histidines 12 and 119 and lysine 41 are connected with the activity of the enzyme. The locations of 2'-cytidylic acid and a homocysteinyl residue which are both known to inhibit enzyme activity can therefore be used to assist in delineating the molecule.

Barnard and Ramel<sup>19</sup> showed that 2'-cytidylic acid binds strongly to the enzyme, acting as an inhibitor. Fig. 7b (compare Fig. 7a) shows that the cytidylic acid, located by difference Fourier synthesis, is found in the cleft in the density distribution. Thus in the neighbourhood of this nucleotide there ought to be those portions of the polypeptide chains carrying the two histidines, 12 and 119, and lysine 41.

Shall<sup>20</sup> was able to prepare two homocysteinyl ribonucleases, one of which (homocysteinyl RNase (2)) was inactive. This would indicate that the homocysteinyl group had been attached to lysine 41, and there is other chemical evidence for this<sup>20</sup>. (Hirs *et al.*<sup>21</sup> have shown conclusively that reaction of lysine 41 with 1-fluoro-2,4-dinitrobenzene (FDNB) results in inactivation of the enzyme.) A difference Fourier map showed a column of density indicating the mercury atom and possibly a part of the homocysteinyl group attached to it. This column of density is shown in Fig. 7c. Two points must be noticed: (1) the region of positive density lies in the cleft of the density distribution model; (2) this column of density itself lies in the neighbourhood of a heavy region of the density distribution (see Fig. 7c), which is clearly a connecting region between two polypeptide chains and is most likely to be the region containing cysteine II-VII (see later).

### The Other Cysteine Residues

The location of another cysteine follows reasonably well, given that II-VII has been found. There are in the

Fig. 5. Packing of the molecules projected along 010.

distribution two sinuous regions of density that start from II-VII and which follow independent paths to a heavy region at the farther end of the cleft (see Fig. 4a and Fig. 4b). From the distribution of sinuous regions of density emerging from it, this second peak provides strong evidence for placing a cystine in this region. If this were a cystine region then it is likely that it would be either III-VIII or I-VI, and the latter, from considerations of chain length, can be eliminated in the following way. Close to what is most likely to be the phosphorous end of the 2'-cytidylic acid peak is a peak which encloses the cleft and could be one end of the chain. This is connected to the cystine region in question by a short region of density. As the amino end of the chain has twenty-five residues before a cystine occurs, it is likely that this peak must be the carboxyl end, which has only fourteen residues (see Fig. 4c). Given that this peak represents a turning back of the carboxyl end of the chain on itself, then the cystine in question can only be III-VIII.

The electron density distribution does not indicate unambiguously the location of the remaining cystines, IV-V and I-VI, but by using the known sequence in conjunction with the electron density map, it is possible to draw some conclusions about their locations. Cystine III-VIII (see Fig. 1) is connected to IV-V by six amino-acids and this, in turn, is connected to I-VI by a single length of chain containing eleven amino-acids. About 15 Å from III-VIII, in a direction along *a*, is a peak which has the appearance of a cystine, which, because it is so close to III-VIII, can only be IV-V (see Fig. 3b). This region lies on the other side of the model and is not visible from the photograph. There remains only one suitable region in the ring of density where I-VI can be placed because there is only one pathway of high density in the ring connecting those two likely positions for the remaining cystine residues. This region is visible in Figs. 4b and c. Given that the four cystines have been located it is possible to envisage a schematic picture of the polypeptide chain and this is discussed in further detail in the following sections.

#### Previous X-ray Studies

Evidence that the cystine positions suggested here are probably correct comes from an earlier completely independent analysis of ribonuclease carried out from a single isomorphous study of this enzyme<sup>18,22</sup>. Here only

the main argument will be reiterated—namely, the location of the cystine residues in the molecule.

In that work three three-dimensional Fourier distributions were calculated, phased from two mercury atoms per protein molecule. These maps were at levels of 6 Å, 3.5 Å and 2.5 Å resolution, respectively, using in each case about 65 per cent of the possible reflexions. It was argued that if the phasing of the X-ray reflexions was approximately correct then there should be evidence from a comparison of the three partial electron density distributions for the presence of the four cystine residues as found by Hirs, Moore and Stein.

Because the X-ray evidence<sup>23</sup> shows that there is little  $\alpha$ -helical conformation in this molecule, and owing to the poor resolution of the higher order maps as a result of partial phasing of the X-ray reflexions, it was argued that pairs of sulphur atoms should be more easily recognized as single heavy peaks than the single sulphur atoms of methionine residues. The 6 Å distribution (which closely resembles the 5.5 Å distribution already discussed) showed five heavy regions, four of which increased in weight in going from the 3.5 to the 2.5 Å maps. Furthermore, a plot was made of the integrated electron density of each heavy region against the local peak height. Integration was performed over a sphere of radius 3 Å, because this would be large enough to contain two sulphur atoms and two  $\beta$ -carbon atoms of a cystine residue. In this way four outstanding regions having both large peak height and

Fig. 6. Projection of the heavy atom positions along (a) 010 and (b) 100.

Fig. 7. Photographs of a model of the electron density showing (a) the "cleft"; (b) the cytidylic acid located in the "cleft"; (c) the Hg-homocysteinyl group located in the "cleft".

integrated density were located corresponding to the same four regions which had increased in weight in going from 3.5 Å to 2.5 Å resolution. These four cystine positions lie on or near the positions already indicated from the present investigations. Their locations are indicated by crosses in Figs. 4a, b, c. It is noticeable that they lie in the crude ring of density shown in Fig. 4b.

The approximate co-ordinates of the cystines are as follows:

III-VIII	$x = 0.00, y = 0.75, z = 0.14$
II-VII	$x = 0.22, y = 0.85, z = 0.45$
IV-V	$x = 0.94, y = 0.45, z = 0.46$
I-VI	$x = 0.69, y = 0.45, z = 0.09$

#### Possible Arrangements of the Polypeptide Chain

Because the four cystine cross-links, at that time, had been located and identified with some confidence, an attempt was made to find the arrangement of the polypeptide chain with respect to them. In this study<sup>18</sup>, a possible conformation was found by a comparison of the 6 Å and 2.5 Å electron density maps, and by model building observing stereochemical principles. With the exception of the amino end of the chain, which was thought to be unsatisfactorily placed at the time the model was built (1961), the path of the chain is schematically shown by the string of dots superimposed on the latest 5.5 Å electron density map, Figs. 4a, b and c.

There is an almost one-to-one correspondence between the model of the molecule based on this previous work and the latest electron density distribution. There is a clear indication now from the recent work that the part of the amino end of the chain in the neighbourhood of histidine 12 approaches histidine 119 in the carboxyl end of the chain, at one end of the cleft, and that lysine 41 lies towards the other end of this cleft. If the cystines have been correctly located, then this 5.5 Å Fourier distribution is in agreement with the previous X-ray investigations and reveals the conformation of the polypeptide chain. The photograph of the wooden model is, in fact, a crude representation of the molecule as we now see it, and Fig. 8 is a wire model showing the approximate arrangement of the backbone of the polypeptide chain.

There is some evidence, from an examination of the anomalous X-ray scattering from the uranium atoms, that the wrong enantiomorph may have been chosen.

We thank Dr. E. A. Barnard, of King's College, London, and Dr. H. Witzel, of the University of Marburg, for the

gifts of 2'-cytidylic acid. Co-crystallizations of ribonuclease with this nucleotide were carried out at both Birkbeck and Sussex.

We collectively acknowledge the help we are receiving from the Science Research Council, the Medical Research Council\* and Birkbeck College which is making this work possible, and we thank Professor J. D. Bernal for his advice and encouragement in all aspects of this work.

*Note added in proof by Dr. C. H. Carlisle, January 30, 1967.*

At the recent conference on "Protein Structure" held in Madras, January 18-21, 1967, Dr. Harker, Dr. Kartha and their co-workers of the Roswell Park Memorial Institute, Buffalo, N.Y., have put forward a model for ribo-

\* Dr. Shall is the recipient of a grant from the Medical Research Council.

Fig. 8. A wire model showing the path of the polypeptide chain.

nuclease based on an electron density map calculated at 2 Å resolution. This model and that proposed above show significant differences in two respects. First there are differences in the electron density maps themselves, and second there are differences in interpretation of the parts of the maps which are the same. There are two regions common to both which have been interpreted as cystines, but these have been identified differently. The one that we have labelled II-VII, and which was identified by the location of the mercurated homocysteinyl group chemically attached to the neighbouring lysine 41, has been labelled I-VI by Dr. Harker. The remaining two cystines are quite widely different.

The second important difference concerns the active site. Dr. Harker has identified this region by the location of a phosphate and arsenate binding site in the crystal, whereas in our work we used the strongly binding inhibitor cytidine 2'-phosphate. We have additional evidence in that the mercurated homocysteinyl group attached to lysine 41 lies in almost the same position as the nucleotide inhibitor, and this chemical modification of the enzyme is known also to be inactive.

When details are published by Dr. Harker and his co-workers, it will be interesting to assess the differences between their findings and the structure we have described in this communication.

### Specific Derivatives of Ribonuclease for Crystallographic Determination of the Protein Structure

THE X-ray diffraction studies on bovine pancreatic ribonuclease described in the preceding article required the preparation of several different isomorphous crystals, each of which contained one or a few stable, heavy atoms at defined locations in the crystal. Knowledge of the site of attachment of the heavy atom makes possible the identification of regions of the electron density maps. This article describes the methods which were used to synthesize the specific derivatives.

### Mercurial Mercaptides of Ribonuclease

In the first step (thiolation) of the synthesis of the derivative, a side-chain carrying a reactive thiol group was introduced into the ribonuclease molecule, as a site for heavy atom complexing. The reaction of *N*-acetyl-homocysteine thiolactone (AHTL) with amino groups<sup>1,2</sup> was applied for this purpose. This reaction is normally non-selective<sup>3</sup>, giving mixtures of a large variety of products; here, it was rendered specific by using very low reagent concentrations and by use of silver ion<sup>2</sup> as catalyst.

**Thiolation reaction of ribonuclease.** Ribonuclease A nitrate was prepared from commercial ribonuclease by chromatography<sup>4</sup>, dialysis, deionization and neutralization. It was reacted with DL-AHTL (recrystallized, melting point 111°C) and silver nitrate, on a radiometer pH-stat, at room temperature; the concentrations used and the enzyme inactivations obtained are illustrated in Table 1 for some experiments at pH 7.5. Enzyme inactivation could be obtained with the use of only slightly more than 1 equiv. AHTL/mole of protein (Table 1). More than 1 equiv. silver/mole of AHTL was needed, however, for full inactivation.

Table 1. REACTION OF RIBONUCLEASE A NITRATE WITH AHTL AND SILVER NITRATE

Experiment	Ribonuclease A (mmolar)	AHTL (mmolar)	Ratio*	Silver nitrate	Final activity† (per cent)
(1)	0.31	1.26	4.1	1.24	3
(2)	0.02	3.30	3.3	15.0	<0.1
(3)	0.36	0.95	2.6	4.0	<0.1
(4)	0.38	0.83	2.2	3.28	<0.1
(5)	0.34	0.66	1.9	1.04	4
(6)	0.20	0.27	1.4	2.23	9
(7)	0.64	0.69	1.1	3.27	5

The reaction was conducted at pH 7.5, 20°–23° C, 30 min.

\* Molar ratio of AHTL to ribonuclease.

† Enzyme activity as a percentage of the original activity.

Two protein products were formed, each thiolated at a different site. This was shown by chromatographic separation after alkylation of the introduced homocysteinyl-SH groups with <sup>14</sup>C-iodoacetate. The main products were always two well separated, mono-substituted, homogeneous protein peaks, one inactive and the other with 100 per cent of ribonuclease activity. This latter derivative (termed homocysteinyl-RNase-1) is enzymatically active in the thiol form and in the *S*-carboxymethyl form, but is reversibly inactivated by silver ions.

Both the two main products (Fig. 1) showed, on amino-acid analysis (using the Beckman Spinco analyser and standard methods<sup>5</sup>), 1 mole of *S*-carboxymethylhomocysteine/mole of protein, but no other significant change in any of the amino-acids of ribonuclease A. It was shown that neither of these derivatives involved a change at the disulphide bonds. Thus, *S*-carboxymethylcysteine was absent in the amino-acid analyses. No inactivation occurred when ribonuclease was incubated alone with the separate components of the reaction mixture, or their products. The dependence of the thiolation reaction on the pH value was a further indication that disulphide interchange was not responsible for the enzyme inactivation.

Amino groups are the sole site of reaction between AHTL and proteins<sup>1,2</sup>. That this was also so in the specific reaction with ribonuclease was shown by repeating the reaction with ribonuclease in which lysine ε-amino groups were altered by guanidination. Two specific derivatives, prepared by Glick and Barnard<sup>6</sup>, in which the number of lysine residues blocked by the guanidino group had been shown to be 9 (an enzymatically active derivative) and all the possible 10 (an inactive derivative), respectively, were used. Each was reacted with AHTL as for ribonuclease A, and then carboxymethylated with <sup>14</sup>C-iodoacetate. The active derivative became mono-substituted (as shown by the incorporation of carbon-14) and inactivated. The inactive derivative, on the other

Fig. 1. Chromatography of *S*-carboxymethyl-(*N*-acetyl)-homocysteiny-ribonuclease *A* derivatives. Ribonuclease *A* nitrate (0.34 mmolar) was reacted with AHTL (1.11 mmolar) and silver nitrate (1.71 mmolar) at 22° C and pH 7.5, in a total volume of 10.0 ml. Enzyme activity dropped to 5 per cent of normal. The silver was removed with potassium cyanide and ion exchange and the free thiol groups were alkylated with 2-<sup>14</sup>C-iodoacetate. The overall yield of protein was 95 per cent. The products were separated chromatographically on an 'Amberlite IRC-50' column (1 × 40 cm), using 0.17 molar sodium phosphate at pH 5.95 as eluant. The effluent was collected in 1.45 ml. fractions; on each fraction, protein concentration (O) was determined (by absorbance at 280 mμ), radioactivity (●) in 0.100 ml. aliquots, and enzyme activity<sup>11</sup> (x) on cytidine 2',3'-phosphate.

hand, showed no incorporation. Thus, the one free lysine group in the active guanidinated derivative contains the ε-amino group the acylation of which in ribonuclease leads to enzyme inactivation. The evidence<sup>6</sup> on these guanidinated derivatives indicates (by the occurrence and rate of the specific dinitrophenylation<sup>7</sup> reaction) that this last remaining ε-amino group is at lysine 41.

An active centre character for the silver-catalysed reaction that produces homocysteiny-*RNase-2* is indicated by the great efficiency of that inactivation at about equimolar reagent ratio, and also by a protection exerted by sulphate ion on the reaction site. The sulphate ion is an inhibitor of the enzyme and active centre alkylation reactions of ribonuclease<sup>8,9</sup>. 50 per cent protection of the inactivation at pH 6.0 was obtained with 13 mmolar sulphate, consistent with its affinity for the active centre near that pH (ref. 4). Protection by more tenacious inhibitors could not be tested because they form complexes with silver ions.

### Crystals containing Heavy Atoms

The synthesis of heavy atom-containing crystals was effected by treating ribonuclease *A* with AHTL and silver nitrate as already described at pH 7.5, at room temperature for 30 min. This gave rise to two isomeric *S*-Ag-(*N*-acetyl)-homocysteiny-ribonuclease *A* derivatives. The silver was removed by complexing with 0.1 molar potassium cyanide, followed by dialysis or ion exchange with chloride, and *p*-hydroxymercuribenzoate was then added to form the *S*-mercuric mercaptide of each isomer. The two isomers were separated from one another by chromatography at pH 5.95 in 0.17 molar phosphate buffer. Again, two main components were resolved, one of which was enzymatically 100 per cent active and the other inactive. Each derivative was dialysed and freeze-dried. The derivatives were crystallized at pH 5.6 in 50 per cent (v/v) ethanol. These crystals were used in the X-ray analysis described in the preceding article.

The value of the derivatives described in this article can be assessed from the X-ray crystallographic work described in the preceding article. They have provided isomorphous heavy atom-containing crystals suitable for phase determination. In this respect they have been

used in conjunction with conventional heavy atom-containing crystals; the two methods are complementary. While only one of the two homocysteiny-*RNase* derivatives has been used for phasing, in fact both derivatives would be suitable for this purpose.

Of special interest is the fact that these derivatives contain substituents at defined, known positions. Such information has been of value in the interpretation of the electron density maps. In particular, the *p*-mercuribenzoate mercaptide of the homocysteiny-*RNase-2* has been shown by the evidence presented in this article to have the homocysteine on lysine 41. This identification locates an element associated with the active site (lys-41) and also permits the possible identification of cys-40, and the associated disulphide bond (II-VII). The X-ray observations (preceding article) show that the 2'-cytidylic acid is located in the neighbourhood of the heavy atom in homocysteiny-*RNase-2*. This indicates the proximity of lysine 41 and the 2'-cytidylic acid. Chemical evidence implicates histidine 12, histidine 119, and lysine 41 in the binding of 2'-cytidylic acid<sup>10,11</sup>.

This method could be developed further. Instead of two singly substituted derivatives, it would clearly be worthwhile to synthesize the doubly substituted compound.

The specificity of the reaction which leads to the enzymatically active derivative (homocysteiny-*RNase-1*) probably rests on the reaction conditions which have been devised. The AHTL/Ag<sup>+</sup> reaction, therefore, is probably fairly generally applicable for the preparation of derivatives suitable for X-ray crystallographic investigations.

The specificity of the AHTL thiolation which leads to the inactive derivative, on the other hand, appears to involve an active centre interaction of one silver ion which leads to a specific local aminolysis. Such enzymes as are inhibited by silver ions in cases where this is not by reason of mercaptide formation should be examined by the AHTL/Ag<sup>+</sup> reaction, because this may yield further information about the interaction of lysine and imidazole groups at the active centres of enzymes.

The present work was supported by grants from the M.R.C. and the Wellcome Trust.

# Polarography of Proteins containing Cysteine

by

G. RUTTKAY-NEDECKÝ

A. ANDERLOVÁ

Institute of Virology,  
Czechoslovak Academy of Sciences,  
Bratislava 9, Czechoslovakia

Polarographic characterization of tobacco mosaic virus and cytochrome *c* reveals the typical "double wave" phenomenon of proteins. By varying the temperature, pH and composition of the supporting electrolyte the two "catalytic maxima" can be resolved into three. It would seem probable that the three catalytic maxima are caused by the cysteinyl residue present in both TMV and cytochrome *c*.

BRDIČKA was the first to report that proteins containing cysteine and cystine in solutions of hexamminecobalt (III) chloride or cobalt (II) chloride, ammonium chloride and ammonia give a characteristic polarographic effect<sup>1</sup>. The phenomenon has been called the "protein double wave" (for review, see ref. 2). Under "standard conditions", that is, at 0° C and in a supporting electrolyte with a composition of 0.001 molar hexamminecobalt (III) chloride, 0.1 molar ammonium chloride, and 0.1 molar ammonia, tobacco mosaic virus (TMV) and its "native" A-protein give only the first part of this protein "double wave"<sup>3,4</sup>. The effect is manifested by a sharp catalytic maximum the peak of which is situated at about -1.5 V compared with the bottom mercury electrode (henceforth called maximum *B*). After heat denaturation or denaturation by treatment with phenol the TMV protein, under "standard conditions", prevalently shows the second part of the "double wave"—the first part is very low and overlapped by the second one<sup>4</sup>. The latter is characteristic of a sharp catalytic maximum, but its peak is situated at about -1.6 V (henceforth called maximum *C*) instead of at -1.5.

Shortly after we had started to use these "standard conditions" for the polarographic investigations of the TMV protein, we observed a slight inflexion on the positive branch of the maximum *B* (especially at high virus concentrations) at about -1.4 V; it seemed probable that this was caused by a new catalytic wave<sup>5</sup>. In further experiments, which are briefly described here, we identified this slight inflexion as a new catalytic maximum (henceforth called maximum *A*). Under "standard conditions" maximum *A* is almost entirely overlapped by the maximum *B*, but can be visualized by raising the temperature of the polarographed solution. We also found the three catalytic maxima *A*, *B* and *C* with cytochrome *c*. With this compound it was possible to demonstrate the appearance of maximum *A* and its separation from maximum *B* much more easily than with TMV. These findings show that, at least with the two proteins mentioned, the traditional "double wave" is in fact formed of three "waves", or more exactly of three catalytic maxima.

The experimental procedure used during the polarographic determination was essentially the same as that previously described<sup>4</sup>. The polarographic curves were registered from -0.8 V (compared with the bottom mercury electrode) with intervals of 0.2 V on the abscissa, a galvanometer sensitivity of  $2.5 \times 10^{-8}$  amp/mm/m, a mercury flow rate of 4.75 mg/sec. a dropping time of 2.1 sec, using a model LP 55 polarograph. The supporting electrolyte consisted of 0.001 molar hexamminecobalt (III) chloride, 0.1 molar ammonium chloride and 0.01–1.0 molar ammonia. The pH with 0.1 molar ammonia was 9.4. The concentrations of TMV and cytochrome *c* in the polarographed solution are given in the legends to

Figs. 1–5. The solutions under investigation, the constituents of the supporting electrolyte and the capillary were all thermostated before and during the polarographic analysis at the temperatures indicated. The recording of the polarographic curve was commenced 4 min after the virus or cytochrome *c* had been mixed with the supporting electrolyte. For each polarographic analysis a new TMV or cytochrome *c* solution was used. A TMV preparation which had been purified by precipitation with ammonium sulphate combined with repeated differential centrifugation, and a horse heart cytochrome *c* preparation, were used throughout the experiments.

Curve 1 of Fig. 1 represents the polarographic effect of TMV under the "standard conditions". The catalytic maximum *B* appears on the cobalt limiting current at about -1.5 V. The catalytic maximum *C* in this example is very low and therefore difficult to discern. Nevertheless, it rises with temperature in the range 0°–25° C, but then decreases together with maximum *B* (curves 2–4, Fig. 1). With rising temperature over the range 0°–25° C, however, the new catalytic maximum *A* becomes observable at about -1.4 V. At 25° C this maximum is greater than either *B* or *C*, and at 37.5° C it predominates in the polarographic effect of TMV. The simultaneous presence of all three catalytic maxima *A*, *B* and *C* at 25° C (pH 9.4) on one and the same polarographic curve of TMV is demonstrated for various viral concentrations in Fig. 2.

The polarographic effect of cytochrome *c* at 0° C closely resembles that of TMV (compare Figs. 3 and 4). Nevertheless, compared with that of TMV, the catalytic maximum *B* of cytochrome *c* is shifted slightly towards more negative potentials. Consequently, with the former substance the appearance of the catalytic maximum *A* during the temperature rise can be followed more easily than with TMV (Fig. 5). With cytochrome *c* the maximum *C* remains low during the temperature increase and is overlapped by the maximum *B*. But here also the

Fig. 1. Variation of the polarographic effect of tobacco mosaic virus (1.8 mg/ml.) with temperature. Curves 1, 2, 3 and 4 were registered at temperatures of 0, 12.5, 25 and 37.5° C, respectively, starting from -0.8 V with intervals of 0.2 V along the abscissa and the galvanometer sensitivity reduced to 1/150. Supporting electrolyte: 0.1 molar ammonia, 0.1 molar ammonium chloride, 0.001 molar hexamminecobalt (III) chloride. The three catalytic maxima are marked *A*, *B* and *C*.

maximum *C* becomes apparent if the concentration of ammonia in the supporting electrolyte is raised to 1.0 moles/l. at 0° C. Under these conditions the maximum *D* is shifted towards more positive potentials, and this is accompanied by a considerable rise of the maximum *C* (Fig. 4). The latter effects are also encountered with TMV (Fig. 3).

A paradoxical phenomenon is apparent when curve 1 in Fig. 4 is compared with curve 4 in Fig. 5: both curves result from cytochrome *c*, and show what seem to be "double waves". The former curve, however, is composed of maxima *B* and *C* and the latter of maxima *A* and *B*. This becomes evident from curve 3 in Fig. 4 and curve 1 in Fig. 5 (both are recorded under identical "standard conditions" and show practically only one catalytic maximum, namely, *B*) and the progressive appearance of maximum *C* in Fig. 4 (curves 3, 2 and 1) and of maximum *A* in Fig. 5 (curves 1–5).

Cytochrome *c* was first studied polarographically by Carruthers<sup>6</sup>, who showed that when it is polarographed in 1.0 molar ammonia, 1.0 molar ammonium chloride and 0.001 molar hexamminecobalt (III) chloride at room temperature it gives a single catalytic maximum the peak of which is situated at about -1.5 V compared with a saturated calomel electrode. Analysing cytochrome *c* under identical conditions we found that maxima *A* and *B* closely approached each other, thus forming a single high peak which almost completely overlapped the much lower maximum *C*.

Maxima *A*, *B* and *C* bear no relationship to the so-called "prenatrium wave" of proteins (see ref. 2) or to the waves III and IV of the octapeptides oxytocine lysine-vasopressin and arginine-vasopressin which appear in solutions of hexamminecobalt (III) chloride, ammonium chloride and ammonia<sup>7</sup>. In contrast to the catalytic maxima *A*, *B* and *C*, these waves show a rapid decrease with increasing pH and ammonia concentration, are

Fig. 2. Variation of the polarographic effect of tobacco mosaic virus at 25° C with the viral concentration. Curves 1, 2, 3 and 4 were registered at TMV concentrations of 0, 0.18, 0.54 and 1.8 mg/ml., respectively, in the supporting electrolyte with the same composition as in Fig. 1, starting from -0.8 V, with intervals of 0.2 V along the abscissa and the galvanometer sensitivity reduced to 1/150. Marks *A*, *B* and *C* are the same as in Fig. 1. The non-catalytic cobalt maximum occurring at about -1.2 V on curve 1 is partly suppressed by TMV on curve 2 and completely on curves 3 and 4. Note the simultaneous presence of all three catalytic maxima *A*, *B* and *C* on curves 2–4.

Fig. 3. Variation of the polarographic effect of tobacco mosaic virus (1.8 mg/ml.) at 0° C with the concentration of ammonia in the supporting electrolyte which also contained 0.1 molar ammonium chloride and 0.001 molar hexamminecobalt (III) chloride. Curves 1, 2, 3 and 4 were registered at ammonia concentrations of 0.3, 0.1, 0.03 and 0.01 moles/l., respectively, starting from -0.8 V with intervals of 0.2 V along the abscissa and the galvanometer sensitivity reduced to 1/150.

Fig. 4. Variation of the polarographic effect of cytochrome *c* (50 µg/ml.) at 0° C with the concentration of ammonia in the supporting electrolyte which also contained 0.1 molar ammonium chloride and 0.001 molar hexamminecobalt (III) chloride. Curves 1, 2, 3, 4 and 5 were registered at ammonia concentrations of 1, 0.3, 0.1, 0.03, 0.01 moles/l., respectively, starting from -0.8 V at intervals of 0.2 V along the abscissa with the galvanometer sensitivity reduced to 1/200. The maximum appearing at about -1.3 V is the non-catalytic cobalt maximum and has no relation to proteins, except that it is suppressed by them (see Fig. 2). Note the appearance of the catalytic maximum *C* with increasing ammonia concentration.

Fig. 5. Variation of the polarographic effect of cytochrome *c* (50 µg/ml.) with temperature. Curves 1, 2, 3, 4 and 5 were registered at temperatures of 0, 12.5, 25, 37.5 and 50° C, respectively, starting from -0.8 V at intervals of 0.2 V along the abscissa with the galvanometer sensitivity reduced to 1/200. The supporting electrolyte had the same composition as in Fig. 1. Note the appearance of the catalytic maximum *A* with increasing temperature.

poorly developed and occur on the steep current intensity rise caused by the discharge of the ammonium ions between -1.8 and -2.0 V compared with a saturated calomel or bottom mercury electrodes.

Of all the amino-acids present in TMV, only cysteine gives a polarographic catalytic maximum comparable with that of a protein<sup>2</sup>. Cucumber virus 4 is biologically closely related, morphologically identical and structurally very similar to TMV, and contains all the amino-acids present in TMV with the exception of cysteine. Besides being polarographically inactive in the native state, cucumber virus 4 is also inactive in its denatured state<sup>4</sup>. Thus cysteine appears to be responsible for the catalytic maxima found in the polarographic effect of TMV. Because the protein of TMV is composed of identical polypeptide sub-units—each containing only a single cysteinyl residue (see ref. 8)—it would seem that one and the same cysteinyl residue is capable of giving rise to all three catalytic maxima *A*, *B* and *C*, or to any one or two of them. (The effect would, of course, depend on its environment or state and on the external conditions such as temperature, pH and the composition of the supporting electrolyte.) It is therefore probable that by suitable variation of the conditions of polarography the three catalytic maxima can also be resolved for other proteins.

# Membrane Phospholipid Synthesis and the Action of Hormones

by  
J. R. TATA

National Institute for Medical Research,  
Mill Hill, London, N.W.7

Incorporation of precursors of phospholipids, RNA and protein after treatment with growth and developmental hormones suggests a simultaneous control of the rates of production of cytoplasmic RNA and membranes in the cell.

THE increase in the rate of protein synthesis provoked by growth and developmental hormones is often accompanied by the appearance of additional cytoplasmic ribosomes<sup>1</sup>. In experiments in which thyroid hormones were used to accelerate the growth of thyroidectomized rats<sup>2</sup> or to induce metamorphosis in bullfrog tadpoles<sup>3</sup>, a higher proportion of ribosomes was tightly bound to membranes of the hepatic endoplasmic reticulum after hormone-induced increase in the population of ribosomes (and polysomes). Virtually all protein synthesis *in vivo* may occur on membrane-bound ribosomes<sup>4,5</sup>, and so it was important to know how the "new" ribosomes formed on hormone administration were distributed on membranes. This in turn necessitated the determination of the rate of proliferation of cellular membranes, especially those of the endoplasmic reticulum, before and after the application of the stimulus for growth and protein synthesis.

I wish to summarize here some work on the rate of phospholipid synthesis in hepatic membranes of normal, hypophysectomized, thyroidectomized and castrated rats. Livers of bullfrog tadpoles and unfractionated seminal vesicles of rat were also examined. Growth hormone, thyroid hormone and testosterone all enhanced the rate of formation of microsomal and mitochondrial phospholipids of the livers and of unfractionated seminal vesicles of young rats deprived of the endogenous hormones. The three hormones have sufficiently different lag periods of action in their target tissues, and so it was possible to find in each case that the enhancement in the rate of proliferation of microsomal membranes was temporally co-ordinated with the hormone-induced increase in cytoplasmic RNA and protein synthetic activity *in vivo*.

The overall design of the experiments reported here was based on our earlier work on the sequential stimulation by thyroid and other hormones of the rate of RNA and protein synthesis in target cells<sup>2,8</sup>. Measurement of the rate of synthesis of phospholipids was followed by measurement of the incorporation of phosphate labelled with phosphorus-32 and choline labelled with carbon-14 *in vivo* at different time intervals after a single dose of the hormone. Phospholipids were extracted with chloroform and methanol from cell fractions after precipitation and washing with 0.4 normal perchloric acid or 5 per cent trichloroacetic acid, and their identity was established by thin layer chromatography on silica<sup>9</sup>. Subcellular fractionation of the liver and determination of the rate of synthesis *in vivo* of nuclear and cytoplasmic RNA were carried out as described by us earlier<sup>2</sup>. Microsomes were fractionated into smooth and rough membranes in the ultracentrifuge according to Dallner<sup>10</sup> except that 0.01 molar magnesium chloride replaced caesium chloride in the bottom layer of 1.3 molar sucrose. The rate of protein synthesis *in vivo* was estimated from the incorporation into protein of radioactivity from a mixture of amino-acids labelled with carbon-14 (*Chlorella* protein hydrolysate).

The term "membrane" as used in this article refers to the insoluble phospholipid-rich components of nuclei, mitochondria and microsomes derived by differential centrifugation of liver homogenates. In the case of mito-

chondrial and microsomal membranes, their composition in phospholipids, sedimentation characteristics, morphological appearance and constitutive enzymes correspond to those in preparations obtained by other workers<sup>11-13</sup>.

From preliminary experiments, which will be described in detail elsewhere, time intervals of isotopic labelling with phosphorus-32 and choline labelled with carbon-14 approaching the maximum levels of incorporation into phospholipids were selected for comparison of hormonal effects. These corresponded for mitochondria and microsomes from normal rat liver to those described elsewhere<sup>14-17</sup>. Fig. 1 shows the rather similar pattern of

Fig. 1. Incorporation of labelled choline into phospholipids of (■), hepatic nuclei; (▲), mitochondria; and (●) microsomes as a function of time after the injection of (a) 3,5,3'-triiodothyronine (T3) to thyroidectomized rats and (b) human growth hormone (HGH) to hypophysectomized rats. Thyroidectomized rats weighing 140–160 g were injected intraperitoneally with 6  $\mu$ c. of labelled choline chloride (methyl-<sup>14</sup>C, 37.6 mc./mmole) 60 min before they were killed, and hypophysectomized rats weighing 110–130 g received 5.2  $\mu$ c. of the radioisotope 40 min before death. The two hormones were administered subcutaneously. Each point represents the average of four determinations on material pooled from three rat livers.

change produced by a single dose of triiodothyronine or of human growth hormone on the incorporation of labelled choline into the phospholipids of nuclei, mitochondria and microsomes from thyroidectomized and hypophysectomized rats. Growth hormone is usually more effective than triiodothyronine in promoting growth of liver; the latter produces a greater increase in weight when administered in a single dose. Incorporation of labelled choline (and also phosphorus-32) into nuclear phospholipids was less affected, or unaffected, by both hormones than incorporation into mitochondrial and microsomal phospholipids.

The increase in specific radioactivity of phospholipids was followed by a net accumulation of phospholipids, especially in the microsomal fraction (Table 1). Taken together with our earlier work on increases in microsomal and mitochondrial membrane proteins and enzymes<sup>6,7,18,19</sup>, these results suggest a substantial proliferation of membranes after administration of hormone. The effect of thyroid hormones on the proliferation of mitochondrial membrane phospholipids and structural proteins<sup>18,19</sup> is of importance in considering the biogenesis of these organelles<sup>20</sup>.

The rough and not the smooth microsomal membranes are the principal site of protein synthesis, and so we fractionated microsomes obtained at different stages of hormone action before analysing the distribution of phospholipids and RNA. An example of such experiments in which triiodothyronine stimulated the growth of the liver of thyroidectomized rats is summarized in Table 2. There was an increase in specific activity of phospholipids and RNA labelled with phosphorus-32 in both the smooth and the rough membranes as a result of triiodothyronine injection and a shift in the distribution of phospholipid and RNA between the smooth and the rough membranes. A higher proportion of phospholipid and RNA was recovered in the rough membranes from hormone-stimulated animals than from the controls. Newly formed phospholipids in the rough membranes were also more resistant to solubilization with a small amount of detergent (0.18 per cent sodium deoxycholate) than was the total phospholipid of unfractionated microsomes as judged by the differences in specific activity. It is on the synthesis of this phospholipid fraction resistant to detergent that the hormone seems to have the most pronounced effect. When similar experiments were performed in which the animals were killed 10 min after a pulse of labelled amino acids, the greatest protein synthesizing capacity was associated with this 0.18 per cent deoxycholate-resistant component of rough membranes. A shift in the distribu-

Table 1. PHOSPHOLIPID, RNA AND PROTEIN CONTENT OF HEPATIC MICROSOMES DERIVED FROM NORMAL, THYROIDECTOMIZED AND HYPOPHYSECTOMIZED RATS WITH AND WITHOUT TREATMENT WITH 3,5,3'-TRIODO-L-THYRONINE AND HUMAN GROWTH HORMONE

Rats	Treatment	Phospholipid (mg/g of liver)	Phospholipid Protein	RNA (mg/g of liver)
Normal	None	8.70	0.33	5.33
Thyroidectomized	None	6.01	0.24	4.08
	T <sub>3</sub>	7.45	0.27	5.10
Hypophysectomized	None	5.35	0.20	3.69
	HGH	6.30	0.27	4.31

Normal and thyroidectomized rats weighed 130–160 g when killed whereas hypophysectomized rats weighed 120–135 g; 3,5,3'-triiodo-L-thyronine (T<sub>3</sub>) was injected as a single dose of 18  $\mu$ g/rat 48 h before death and 75  $\mu$ g of human growth hormone (HGH) were injected twice, 48 and 18 h before death. Each value is the average derived from four separate determinations on livers pooled from three rats.

Table 2. CHANGES INDUCED IN THE DISTRIBUTION IN MICROSOMAL SUBFRACTIONS OF PHOSPHOLIPIDS AND RNA SYNTHESIZED DURING ACCELERATED GROWTH OF THE LIVERS OF THYROIDECTOMIZED RATS INDUCED BY A SINGLE INJECTION OF TRIIODOTHYRONINE

Fractions	Specific activity of phospholipids (c.p.m./ $\mu$ g of phosphorus)		Relative distribution of phospholipids (per cent)		Specific activity of RNA (c.p.m./ $\mu$ g of phosphorus)		Relative distribution of RNA (per cent)	
	Control	Treated	Control	Treated	Control	Treated	Control	Treated
Microsomes	77.5	185.0	100	100	7.8	15.3	100	100
Smooth membranes	84.9	227.0	40	25	17.5	47.6	6.6	7.9
Rough membranes	79.9	172.0	53	62	6.3	14.9	86.0	74.0
0.18 per cent DOC pellet	95.0	585.0	8	13	3.5	7.9	7.7	18.0

Half of the thyroidectomized rats were treated with 18  $\mu$ g of T<sub>3</sub> for 32h before they were killed; all animals received 75  $\mu$ c. of phosphorus-32 12 h before death. Microsomes were isolated from one aliquot of the supernatant free of mitochondria, and smooth and rough membranes were isolated from another. A part of the rough membrane fraction was suspended in 0.18 per cent sodium deoxycholate (DOC) (20 mg of DOC/3 mg of phospholipid) and the sediment (0.81 per cent DOC pellet) was collected for analysis. Each value is the mean of four determinations made on preparations from three rat livers.

Fig. 2. Incorporation of labelled phosphate into ( $\Delta$ ) RNA and ( $\bullet$ ) phospholipid during the course of growth ( $\times$ ) of seminal vesicles induced by a single injection of testosterone propionate to castrated rats. Male rats weighing 50–60 g were castrated 2 weeks before the experiment in which 50  $\mu$ c. of carrier-free phosphorus-32 was injected intraperitoneally 2–6 h before the death of animals which had received 200  $\mu$ g of testosterone propionate intramuscularly at the different times indicated. Seminal vesicles were weighed, chilled to 0° C, finely chopped and homogenized in 0.15 molar sodium chloride in a Kontes conical all-glass homogenizer before extraction of phospholipids and RNA. Each point is the average value obtained from four determinations in six castrated rats.

tion of microsomal membranes between smooth and rough, with a relative increase in tightly membrane bound ribosomes induced by these hormones, is compatible with sudden acceleration in the rate of growth and protein synthesis. This change is, however, unlike the increase in the smooth relative to rough membrane observed in the liver of rat soon after birth, as recently reported by Dallner *et al.*<sup>16,17</sup>.

As shown in Table 2, a small portion of microsomal RNA is associated with smooth membranes, and we have repeatedly found its specific activity and turnover rate to be greater than that of RNA from rough membranes. A species of rapidly labelled RNA in smooth membranes of rat liver microsomes with sedimentation characteristics and base composition different from all other species of cytoplasmic RNA has been described previously<sup>21–23</sup>. Its role in protein synthesis is still unknown.

In contrast with the mammalian system<sup>2</sup>, there was relatively little accumulation of cytoplasmic RNA after intense labelling of RNA both in the nucleus and cytoplasm at short time intervals after the induction of metamorphosis in bullfrog tadpoles<sup>3</sup>. Table 3 shows that there is, however, a noticeable accumulation of microsomal phospholipid, and also of protein, which accompanies the turnover of microsomal RNA. We have also observed, both by fractionation of microsomal membranes and by electron microscopy, that one of the principal features of induced metamorphosis is a proliferation of rough membranes of endoplasmic reticulum accompanied

Table 3. SYNTHESIS OF HEPATIC MICROSOMAL PHOSPHOLIPIDS, RNA AND PROTEIN FOLLOWING THE PRECOCCIOUS INDUCTION OF METAMORPHOSIS IN *Rana catesbeiana* TADPOLES

Time after induction (days)	Incorporation of phosphorus-32 into		Amount of microsomal (mg/g of liver)		
	Phospholipid (c.p.m./mg P)	RNA (c.p.m./mg of phosphorus)	Phospholipid	Protein	RNA
0	492,000	204,000	2.44	11.0	2.8
1.8	420,000	217,000	2.51	10.1	2.7
3.7	594,000	510,000	2.69	9.6	2.9
6.8	683,000	628,000	3.80	14.2	3.1

Groups of 12 *Rana catesbeiana* tadpoles (with no hind limbs) were injected with 1  $\mu$ g of 3,5,3'-triiodothyronine at the times indicated before they were killed. Labelled phosphate (10  $\mu$ c.) was injected 18.0 h before the animals were killed and the microsomes were prepared as described elsewhere. Each value is the mean of two determinations in duplicate.

by a redeployment of cytoplasmic ribosomes (my own unpublished observations). Mitochondrial phospholipid synthesis was also enhanced concomitantly with an increase in total mitochondrial structures<sup>3</sup>.

Poor recoveries of subcellular fractions from accessory sexual tissues of castrated rats prevented us from fully investigating the formation of phospholipids in microsomal membranes from the prostate and seminal vesicles after growth of the prostate and seminal vesicles had been induced by testosterone. In view of the massive accumulation of RNA and proliferation of membranes in seminal vesicles produced by the administration of the androgen to castrated animals<sup>24</sup>, we investigated the turnover of phospholipids and RNA in unfractionated homogenates of this tissue (Fig. 2). An increased rate of synthesis of total phospholipid was observed at much the same time as the increased rate of bulk RNA synthesis which accompanies the dramatic hypertrophy produced by testosterone in

this organ. It was shown earlier that a single injection of testosterone under similar conditions led to a four- to five-fold increase in bulk RNA/DNA if the tissues were analysed 5 days after treatment with hormone<sup>1</sup>.

Perhaps the most significant point that emerges from these investigations is the timing of the effects of the different hormones on the synthesis of phospholipid in their target cells in relation to the acceleration of the rate of protein synthesis. The magnitude and speed of hypertrophy induced by growth hormone, thyroid hormone and testosterone in the liver of animals in which the rate of growth of the organ was retarded or arrested by deprivation of the hormone followed a distinctive pattern for each hormone. These features are reflected in biosynthetic activities of the target cells, as has already been demonstrated by us in the synthesis of RNA by the nucleus<sup>2,8</sup>.

The data summarized in Fig. 3 show that growth hormone stimulated the protein synthetic capacity of hepatic microsomes *in vivo* several hours earlier than did testosterone or triiodothyronine. This change accompanied the appearance of additional microsomal RNA or ribosomes (see also refs. 1 and 2). The onset of increase in the rate of microsomal phospholipid synthesis, and eventually the proliferation of rough membranes, coincided for each hormone with the foregoing two effects. It is also interesting to compare the magnitude of these effects produced by testosterone in the liver and seminal vesicles of the same castrated rats. The rate of growth of the accessory sexual gland is several times more sensitive to the androgen than is that of the liver (a single injection of 250  $\mu$ g of

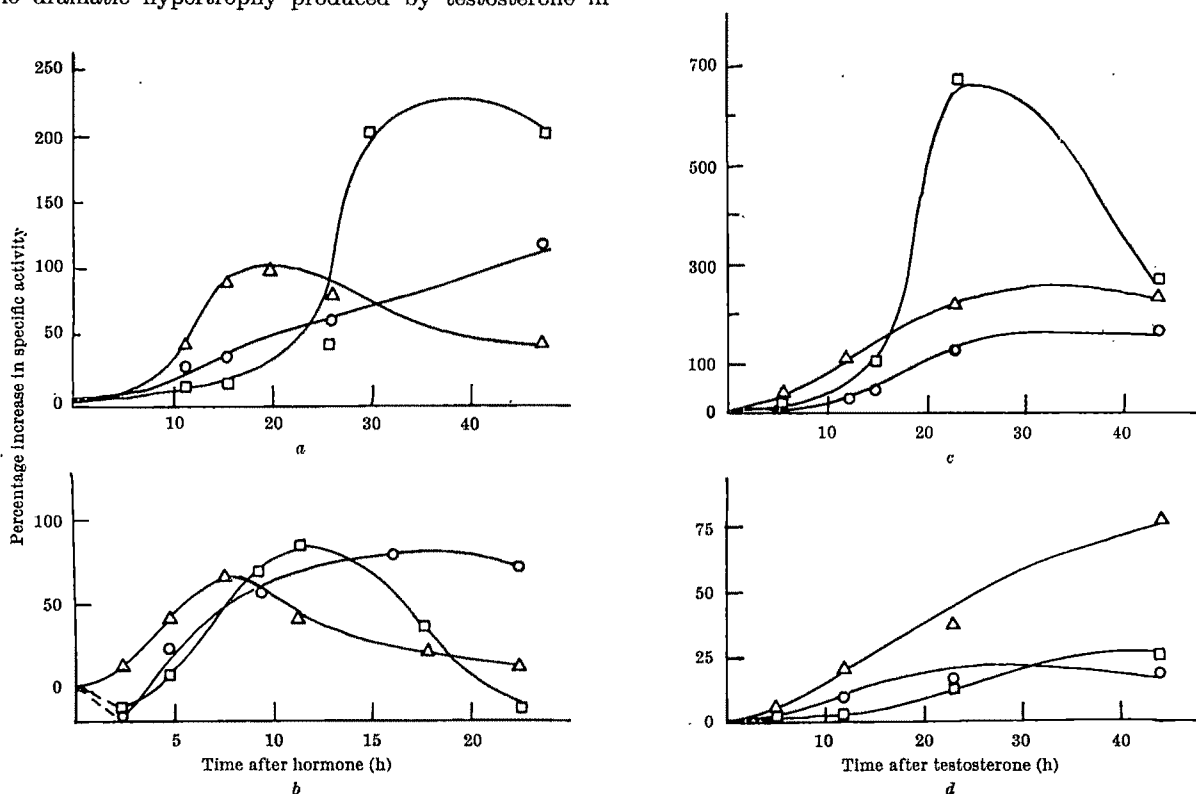

Fig. 3. Co-ordination of the synthesis of microsomal phospholipids with the appearance of labelled RNA in microsomes and their capacity *in vivo* to incorporate amino-acids into protein after hormone-induced growth of liver and seminal vesicles. The rate of microsomal RNA and phospholipid synthesis in the liver and of total RNA and phospholipids in seminal vesicles was determined from the incorporation of radioactivity into the macromolecules 9–11 h after the administration of 60–75  $\mu$ c. of phosphorus-32. The rate of protein synthesis *in vivo* was estimated from the incorporation of radioactivity into proteins after the administration of 4–7  $\mu$ c. of a mixture of amino-acids labelled with carbon-14 (*Chlorella* protein hydrolysate; 600  $\mu$ c./mg) 10 min before death in experiments with liver microsomes and 20 min in the case of seminal vesicles. (a) Stimulation observed in liver microsomes caused by a single injection of triiodothyronine to thyroidectomized rats; (b) changes produced by a single injection of 75  $\mu$ g of GHG in hepatic microsomes from hypophysectomized rats; (c) stimulation of the rates of macromolecular synthesis in unfractionated seminal vesicles of castrated rats at different times after a single injection of 250  $\mu$ g of testosterone propionate; (d) the effect of testosterone administration on hepatic microsomes from castrated rats similar to those used in (c). For incorporation of phosphorus-32 the same rats were used in (c) and (d). An important point to note is the wide differences in the scales of ordinates and abscissae of the four diagrams. The drop in the specific radioactivity of nascent protein at the later time-intervals is mainly a result of the substantial increase in membrane and ribosomal protein content of microsomes. The results are expressed as percentage increase in specific activity of (O), phospholipid; (□), RNA; and (Δ), protein in hormone-treated animals for the values obtained in preparations from untreated controls.

testosterone increased the weight of seminal vesicles of castrated rats by 200 per cent in 4 days, whereas liver weight increased by only 6 per cent–8 per cent). It is therefore interesting to see that responses of these two tissues in terms of rates of synthesis of macromolecules are of comparable order (compare Fig. 3c and d). The time of onset of the stimulatory effect was, however, the same in both tissues.

In conclusion, it seems that the regulation of the rate of protein synthesis by growth and developmental hormones involves a simultaneous control of the rates at which cytoplasmic RNA and membranes are generated in the cell. A concomitant proliferation of membranes of the endoplasmic reticulum and redistribution of ribosomes has also been observed in other situations of growth and maturation or enzyme induction<sup>16,17,27,28</sup>. A co-ordinated proliferation of membranes that is geared to the rate of protein synthesis or adaptive functions may be a common property of cells of higher organisms. It should be realized, before any generalizations are made, that the tissues that have been investigated could represent a special case, because they are largely those that elaborate substantial amounts of proteins for export, a function in which microsomal membranes play an important part<sup>29,30</sup>. Besides the hormones that we have investigated, a very pronounced effect of TSH and oestrogen on synthesis of phospholipid in the thyroid and uterus, respectively, has also been observed to occur at about the same time as the acceleration of synthesis of RNA or the onset of biological effects of the hormone<sup>31,32</sup>. Regulation of the proliferation of the membranes and ribosomes may not, however, be the only way in which all hormones control protein synthesis and indeed hormonal control of translational processes preceding a change in the rate of RNA synthesis has been suggested for the action of ACTH and insulin<sup>33,34</sup>. The results described in this paper represent relatively late effects of the hormones in the chain of events leading to growth and maturation, but the specificity and reversibility of their actions can throw much light on the biogenesis and complex functions of cellular membranes.

I thank A. J. Bell and M. Inchley for technical assistance. M. Stack-Dunne performed the hypophysectomies and D. Bangham supplied human growth hormone.

## Effect of Nucleic Acids from Immune Lymphocytes on Rat Sarcomata

by

Primary rat sarcomata regress, usually temporarily but occasionally completely, after the injection of nucleic acids from lymphocytes of sheep and allogeneic rats which have been immunized with tissues from the tumour to be treated. It is possible that the effect results from the strengthening of an already existing immune reaction and that it is only temporary because it is related to the life span of messenger RNA.

PRIMARY fibrosarcomata in the rat, induced by chemicals, can be caused temporarily to regress by treatment with lymphocytes separated from the lymph of animals immunized with the tumour<sup>1</sup>. The specificity with which the lymphocytes act only against the tumour used for inoculation suggests that the phenomenon is immunological. The fact that our later work<sup>2</sup> showed that heterologous lymphocytes from sheep and goats were also effective suggests that the transfer of a sub-cellular factor may be

involved. A similar interpretation might be placed on the experiments<sup>3</sup> in which the growth of these tumours was retarded when the immune lymphocytes were administered inside intraperitoneally placed 'Millipore' chambers. Work from numerous laboratories (see later) suggests that immune reactions can be induced by specific RNA and this led us to explore the possibility of treating tumour-bearing rats with nucleic acids extracted from the immune lymphocytes. The preparation used contained

all the RNA of the cells but was contaminated with some DNA. The rationale of these experiments was that nucleic acids from immune lymphocytes may confer on the tumour-bearing host an increase in the capacity to react immunologically against the tumour specific antigens of the transplantation type known to be present in these primary sarcomata<sup>4</sup>. Both the aim of the present experiments and the method of applying the nucleic acids are quite different from those studies in which it has been alleged that treating tumour cells *in vitro* with RNA from normal cells causes epigenetic changes in malignant cells such that they lose the capacity to give rise to tumours on being transplanted into suitable hosts<sup>5-7</sup>.

Intravenous injection had proved to be the most effective way of administering the immune lymphocytes<sup>1</sup> to tumour-bearing animals, but this route was not chosen in the present experiments with the nucleic acids because it was thought that the high RNase activity of blood would cause inactivation of the RNA before it could be taken up by the lymphoid cells. The injection of the RNA into the footpads ensured that the RNA reached lymph nodes directly and this route of administration has been successfully used in transferring immunity *in vivo* in another system<sup>8</sup>.

Primary fibrosarcomata were induced with pellets of 3 : 4-benzpyrene as described by Haddow and Alexander<sup>9</sup>. Two rats with comparable tumours having a diameter in the range of 1.5–2.0 cm were selected for each experiment. About half the tumour mass was excised from each rat. One of the tumour masses was used for immunization and the other discarded. The techniques of immunizing rats and of obtaining immune thoracic duct lymphocytes from "donor" rats have already been described<sup>1</sup>. In the experiments with sheep lymphocytes the tumour was injected into the drainage area of the prefemoral lymph nodes, the efferent duct cannulated 3 days later and the lymph was collected daily over the next 3 days<sup>2</sup>. The cells from each collection were washed, re-suspended in Hanks solution and quickly frozen at  $-80^{\circ}\text{C}$ .

The nucleic acids were extracted from the cells (see later) and doses containing 0.5 mg of RNA together with variable amounts of DNA were injected in 0.5 ml. saline into the hind footpads of the tumour-bearing rats. The number of cells that could be obtained from the thoracic duct of immunized rats was sufficient for only one treatment, but sufficient nucleic acids to give repeated doses were obtained from the efferent lymph from the nodes of sheep. The injections were repeated as shown in Table 1 either on successive or on alternate days.

In the 7 days between obtaining the tumour for immunization and the injection of nucleic acids, the tumours grew rapidly and experiments in which the diameter at the beginning of treatment was larger than 2.4 cm have not been reported because such tumours tend not to respond to any type of therapy.

Three days after immunization the proportion of large basophilic cells, which, because they are rapidly dividing, we refer to as lymphoblasts, increases in the efferent lymph of the stimulated nodes and their numbers reach a maximum between 90 and 120 h (ref. 10). The degree of response of the nodes to immunization with tumours is assessed by the percentage of these large cells present in the lymph at the peak period; "poor", less than 7 per cent; "moderate", 7–15 per cent; "good", 15–25 per cent; "excellent", greater than 25 per cent—the highest value was 40 per cent. These lymphoblasts contain about six times as much RNA per cell as the small lymphocytes that are also present, and consequently in most of the experiments the main part of the RNA in the nucleic acid preparation was derived from these large lymphoid cells.

Each gram of frozen cells was gently homogenized with 10 ml. of freshly prepared 6 per cent 4-aminosalicylic acid and mixed with an equal volume of 90 per cent phenol

containing 0.1 per cent 8-hydroxyquinoline<sup>11</sup>. After stirring for 30 min at  $0^{\circ}\text{C}$  in a 35 ml. cellulose nitrate centrifuge tube, the layers were separated by spinning at 5,000 r.p.m. for 20 min. The aqueous supernatant containing the nucleic acids was carefully removed using a pipette with a curved end. This was made 3 per cent with respect to sodium chloride and stirred again with one half volume of phenol containing 0.1 per cent 8-hydroxyquinoline for 15 min at  $0^{\circ}\text{C}$ . The nucleic acids in the aqueous supernatant, separated as before, were precipitated by adding two volumes of 10 per cent *m*-cresol in ethanol and standing for 1 h at  $0^{\circ}\text{C}$ . The pellet was spun out at 60 r.p.m. for 15 min, and washed twice with 75 per cent ethanol containing 1 per cent sodium chloride. After draining, the bulk of the DNA was removed by shaking vigorously with 25 ml. of 3 molar sodium acetate (pH 6), and centrifuged at 30,000 r.p.m. for 15 min to ensure recovery of the fine precipitate of RNA. This was repeated three times and the resulting nucleic acids drained and dissolved in a volume of physiological saline to give a concentration of 0.5 mg/ml. of RNA. Recoveries of 1.6–2.3 mg of RNA/g of wet cells were obtained. The preparation was contaminated with less than 1 per cent protein but always contained a substantial fraction of the cells' DNA. In some experiments the material injected contained as much DNA as RNA.

Table 1. RETARDATION OF GROWTH OF PRIMARY RAT SARCOMATA BY INJECTION OF NUCLEIC ACIDS EXTRACTED FROM THE LYMPHOCYTES OF SHEEP AND ALLOGENEIC RATS IMMUNIZED WITH PIECES OF THE TUMOUR TO BE TREATED (In the sheep experiments both the tumour used for immunization and another tumour which had been biopsied only were treated with the nucleic acid.)

\* Measurements based on diameter of tumour at the time of first treatment with nucleic acids.

† Lymphocyte donors immunized with a sarcoma other than the one being treated.

The rate of growth of the different primary fibrosarcomata is remarkably uniform<sup>9</sup> and was determined by regular diameter measurements. These tumours, even after the biopsy procedure used for obtaining material for immunization, never regress spontaneously and any decrease in size must be attributed to treatment. A useful measure for assaying the effectiveness of a treatment is the time required for the tumour diameter to increase by a factor of 1.6 (corresponding for spherical tumours to an increase in volume of four times). In more than a hundred controls which received no treatment

other than biopsy this time was on average 11.5 days and never exceeded 20 days (refs. 1, 2 and 9).

From the lower part of Table 1 it can be seen that all five of the primary tumours treated with RNA from thoracic duct lymphocytes of immunized rats showed temporary regression and in three of the five experiments the time for the tumour to increase its volume by a factor of four was substantially extended. Because the number of lymphocytes that were obtained was relatively small there was usually only sufficient RNA to treat one rat—namely, the one that had been used for immunization—and in only one experiment, No. 526, was it possible to inject also a "control" tumour-bearing rat and this showed no response.

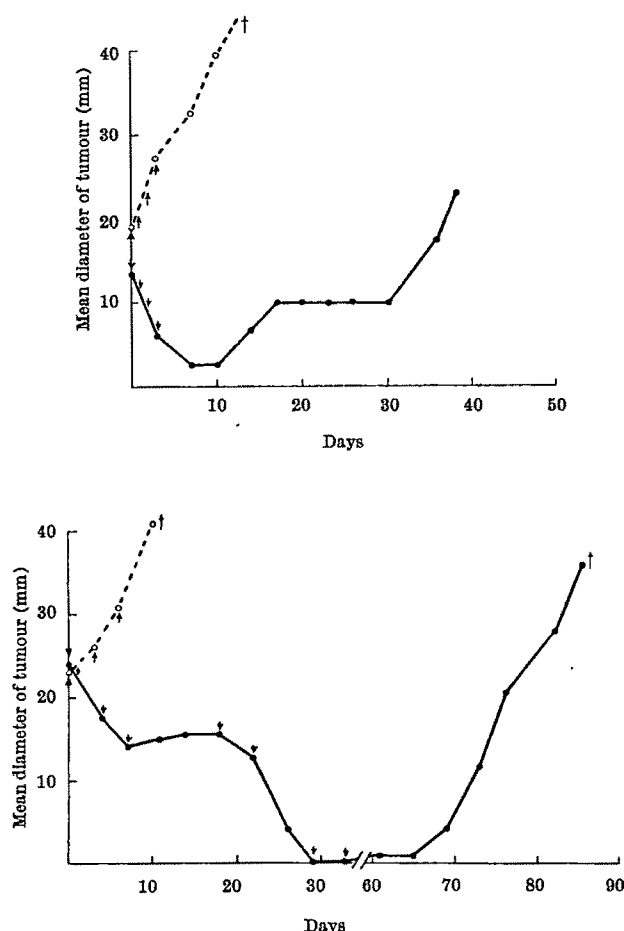

Fig. 1. Growth curves of two pairs of primary rat sarcomata after treatment with nucleic acids extracted from the lymphocytes of sheep immunized with tumour (↓ indicates times of injection of nucleic acids). In each pair the "treated" (●—●) animal provided the tumour for immunization; the "control" (○- -○) also had part of its tumour excised, but this material was not used for immunization.

Nucleic acid from sheep lymphocytes was used in the majority of the experiments and in each case two rats with primary tumours were used and treated with aliquots of the same nucleic acid preparation. Both tumours were biopsied simultaneously, but only one of the tumours was used for immunization; the animal from which this tumour was taken is the "specifically treated" member of the pair while the other is referred to as the control. In none of the seven pairs was the growth of the "control" tumour affected by the RNA (they grew at the same rate as completely untreated tumours) while six of the seven "treated" tumours responded. Fig. 1 shows the growth curves of two pairs of animals in which the "specifically

treated tumour regressed for long periods. The available data suggest, but are not sufficient to establish, a correlation between the response of the draining node in terms of the proportion of basophilic lymphoblasts present and the anti-tumour action of the nucleic acids extracted from the cells in the lymph.

There can be little doubt that nucleic acids derived from lymphocytes issuing from a node stimulated by tumour exert a growth inhibitory effect on the specific primary fibrosarcomata used for immunization although the procedure does not seem to be quite so effective as the intravenous injection of the intact lymphocytes (compare refs. 1 and 2). While direct proof is lacking, the data are consistent with the assumption that the active material is provided by the large lymphocytes rich in RNA which are released from the node as a result of immunization. That this anti-tumour effect of the nucleic acids has an immunological basis involving the tumour specific antigens seems to be indicated by the absence of cross-reaction; the tumour specific antigens of chemically induced tumours have been shown to be unique for each tumour (compare ref. 4).

The very low protein content of the preparation used suggests that a nucleic acid, or possibly a covalently linked nucleic acid-protein adduct, constitutes the active principle. Although the preparation procedure was specifically designed for the isolation of RNA an approximately equal amount of DNA was present. Experiments are now under way with more highly purified materials, but the discussion which follows is based on the assumption that the activity resides in the RNA. If this can be shown to be the case it is still conceivable that the DNA augments the response in a non-specific way by acting as an adjuvant.

In the past 10 years RNA or RNA antigen adducts ("super-antigens") have been shown to be capable of initiating immune responses in a number of systems. The results seem to require that extraneously supplied RNA can act at least at two different points in the sequence of events between the phagocytosis of antigen and the formation of antibody, either free or cell-bound (see Fig. 2). Phagocytic cells in the lymphoid tissues retain antigenic proteins for long periods during which they may be complexed with RNA (refs. 12 and 13). Such RNA complexes are highly immunogenic<sup>14</sup> and may be responsible for the capacity of RNA extracted from macrophages to initiate antibody formation by lymphoid cells *in vitro*<sup>15,16</sup>.

On the other hand, the action of RNA at a different level is indicated: by experiments<sup>17</sup> in which the capacity of lymphoid cells to transfer immunity was temporarily abolished by treatment with RNase, and also by the observation that the capacity to transfer homograft immunity can be bestowed on lymphoid cells by incubating them *in vitro* with RNA extracted from immune cells<sup>18</sup>. Our working hypothesis is that the mechanism by which RNA acts in these latter experiments may be the same as that involved in the anti-tumour action in our experiment. A possible interpretation of the mode of action is based on the concept that the lymphoblasts which are released by the node in response to antigenic stimulation are not principally antibody producers, but are messenger cells<sup>19</sup> that migrate throughout the lymphoid system. In this way an initially local response is propagated throughout the body. Experimental support for this concept was provided by draining off the lymph from the locally stimulated node in sheep. When this was done, no circulating antibody was formed, but on injection of these cells into a chimaeric twin antibody production occurred. The observation<sup>20</sup> that it is the large lymphocytes in the thoracic duct which are responsible for the transfer of delayed hypersensitivity lends further support to this concept.

One can hypothesize (see Fig. 2) that the antigen processed by macrophages and possibly linked to RNA stimulates the node to form the lymphoblasts rich in

RNA. These cells do not propagate the immune response merely as passive vehicles for antigen, and the failure to detect antigen in them strengthens the view that information is passed at a level which does not involve the actual antigen. The simplest hypothesis is that the lymphoblasts proliferate and then differentiate into plasma cells. If that were their only function, then it would be difficult to envisage how they could function on transfer to an allogeneic or even less a heterologous host (that is, sheep basophilic cells in rats)<sup>2</sup>. An alternative mechanism (compare ref. 19) by which the immune response may become generalized is that the lymphoblasts do not survive for any length of time in the lymph nodes to which they have migrated, but that they may convey the immune stimulus by passing a "message" (other than conventional antigen) to the actual antibody forming cells such as the plasma cells.

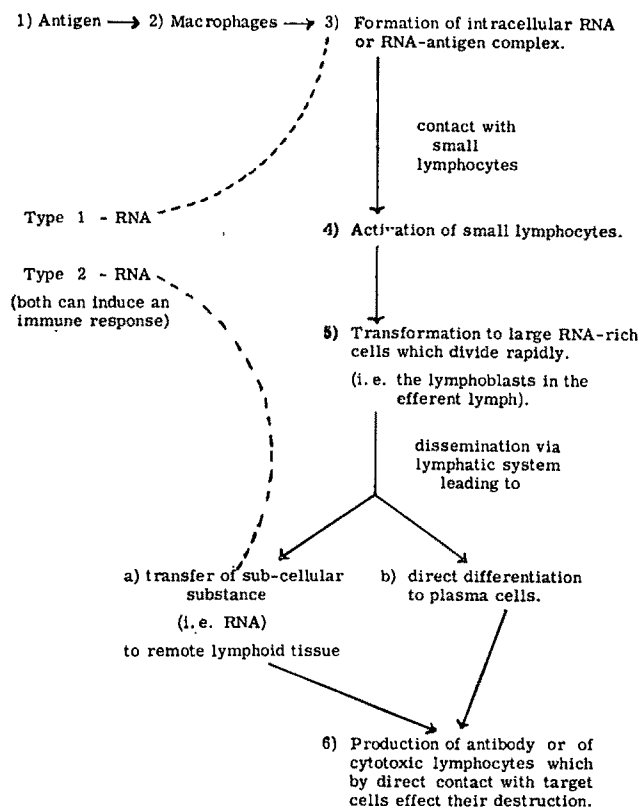

Fig. 2. Diagrammatic representation of a hypothetical sequence of events in the immune response showing stages where externally administered RNA may be active.

The general concepts of molecular biology suggest RNA as a likely candidate for the subcellular message especially as the most characteristic biochemical feature of the lymphoblasts is their high RNA content. These cells are rich in polysomes—which contain the "messenger RNA" clearly identified in protein synthesis—but do not contain the rich endoplasmic reticulum characteristic of cells which produce antibody. Indeed, the use of the term "messenger cell" by Hall *et al.*<sup>19</sup> was indicative of the hypothesis that the message might be the "messenger RNA" of molecular biologists.

The second step in the immune process at which extrinsic RNA can initiate an immune response is, according to this hypothesis, the uptake of RNA by cells capable of producing antibody after receipt of message. This RNA we assume to be different from the RNA of the super

antigen, and in experiments with bacterial antibodies the RNA from the messenger cells, unlike the material isolated by Askonas and Rhodes<sup>14</sup> from macrophages showed no antigenic activity. The tentative explanation of the role of RNA in the present experiment is that under certain conditions the function of the messenger cells may be replaced by administration of RNA from suitably stimulated lymphocytes. This concept is based on the experiments of Hall *et al.*<sup>19</sup> which demonstrate the role of messenger cells in the production or circulating antibody. To apply it to the present experiment it is necessary that an analogous series of steps is involved in the production of cytotoxic lymphocytes because there is no reason to believe that circulating antibody is involved in the anti-tumour action of specifically immunized lymphocytes or their RNA.

It is not necessary to infer from the experiments reported that the injected nucleic acids initiate a primary immune response because there is evidence<sup>4</sup> that the host reacts actively against the specific antigens of the autochthonous tumour even when the response is insufficient to affect significantly the growth of the tumour. The anti-tumour effect of the nucleic acids from the specific lymphocytes—and of the intact cells themselves—may be the result of enhancing an already existing reaction rather than the initiation of a new response. According to this view the production of "message" and not the capacity to carry out instructions received is the factor which limits the extent to which the host is capable of reacting against its own primary tumour. The recurrence of tumour growth after treatment may result from the fact that this reinforced immunity against the tumour specific antigens does not usually persist for long periods and this may be related to the life span of the specifically activated lymphocytes or that of their "messenger" RNA. The procedure can probably cause the total elimination of only small aggregates of tumour cells, but there is no need to emphasize the clinical value of a method which might selectively clear the small numbers of dispersed malignant cells which frequently remain after other forms of therapy. The use of nucleic acids avoids many of the possible complications arising from the use of intact foreign cells—particularly of heterologous origin—and it is difficult to envisage how such a procedure could cause enhancement.

# Patterns of Selections by Monkeys with Lesions of the Cerebral Cortex

by

LAWRENCE WEISKRANTZ  
ROSEMARY MINGAY

The Psychological Laboratory, Cambridge

Monkeys with frontal and inferotemporal lesions show different patterns of responses to an array of objects when offered equally rewarded alternatives.

THERE is considerable evidence that monkeys with lesions of the dorsolateral portions of the frontal cortex are defective in delayed response and similar tasks<sup>1</sup>. Various attempts have been made to characterize such animals as being defective in short term memory<sup>1-3</sup>, but such a description fails to account for all the results. For example, in certain circumstances frontal monkeys are superior to controls in learning simple object discriminations<sup>4,5</sup>, and their retention appears to be good when "the test conditions are such that the normally dominant response does not interfere with correct performance"<sup>6</sup>. Accordingly, one is led to examine stages in the processing of information which are logically before storage. The present investigation is concerned with the manner in which frontal monkeys sample stimuli from a large array, with the situation deliberately designed to make storage of information about particular choices unnecessary.

Twelve rhesus monkeys of varying ages and seven young baboons were used as subjects. They all had previous testing experience in other tasks. Five rhesus and three baboons had received bilateral ablations of the dorsolateral frontal region; three rhesus and two baboons had bilateral ablations of the inferior temporal region; and four rhesus and two baboons were unoperated controls. All testing was carried out in a modified Wisconsin testing apparatus. The test board contained eight food-wells, covered by plaques carrying eight different multi-dimensional objects. The objects remained the same throughout the experiment and were always in the same position. Half a peanut was placed under each object, and the wells remained uncovered after the reward had been removed. Before formal testing began, the animals were accustomed to the apparatus and learned to displace the plaques to obtain the reward. The wells remained uncovered after each response, and so further attempts to select the same object were rapidly extinguished.

When the screen was raised the animals were allowed a maximum of 1 min to select all of the eight objects. This constituted a trial. If all the rewards were removed in less than 1 min, the screen was lowered, and the time of completion recorded. Each animal received six trials a day for 9 days. The order in which the objects were selected was observed through a one-way vision screen and recorded. Testing was carried out 22-24 h after feeding. It became apparent, while testing the first few animals, that some broke off from the task and returned to it, while others completed their selection without interruption. Later, all such "breaks" in performance were recorded; a "break" was defined arbitrarily as an occasion when the animal turned away from the test board, either by looking away or moving away from it physically.

The results for all animals showed a tendency for a stereotyped pattern of selection in that there was a strong likelihood of an object being selected which was adjacent to the one just previously chosen. Fig. 1 shows the percentage of successive pairs of all responses as a function of the relative separation between objects displaced by any response and the immediately preceding response. Fig. 1a shows the complete results and ignores "breaks", and

Fig. 1b shows the results between "breaks". It is evident that not only is the stereotypy quite strong, but that frontal animals display it to a lesser extent than control animals. Table 1 lists the probability values (calculated by Mann-Whitney *U* test) of obtaining differences between frontals and non-frontals by chance.

Table 1. PROBABILITY VALUES OF OBTAINING CHANCE DIFFERENCES BETWEEN THE RESULTS OF FRONTALS AND NON-FRONTALS

	Position of second choice in relation to first				
	Adjacent	Two away	Three away	Four away	
Complete analysis (two tail test)	<0.02	<0.05	<0.02	>0.10	Frontals <i>n</i> = 7 Non-frontals <i>n</i> = 11
Between "breaks" analysis	<0.021	<0.047	<0.021	>0.35	Frontals <i>n</i> = 6 Non-frontals <i>n</i> = 6

A more general, but more precise, analysis can be carried out by considering the chance probabilities of obtaining observed entries in a table of digrams for each response and the immediately preceding response. This was done for each animal on each day of testing using an approximation to  $\chi^2$ . The greater the value of  $\chi^2$ , the greater the stereotypy of the results (independent of the exact type of stereotypy). An animal was considered to show stereotypy if the  $\chi^2$  value for the day in question exceeded the 1 per cent level of significance.

When all trials, irrespective of interruptions, were considered, it was found that frontal animals made significantly fewer selections ( $P < 0.025$ , Mann-Whitney) which satisfied the criterion of stereotypy than did animals with inferotemporal lesions or unoperated controls. The inferotemporal group could not be distinguished from the unoperated group ( $P = 0.3$ , Mann-Whitney) and has therefore been combined with the unoperated animals as the

Fig. 1. a, Percentages of successive pairs of responses, ignoring "breaks", expressed as a function of the relative separation between objects. b, The same, for successive pairs of responses between "breaks". ●, Frontals; ×, normals; and ○, temporals.

"non-frontal" group for comparison. The results are shown in Table 2. The frontals showed less stereotypy than the non-frontals in the analysis both of the complete results and of the results between "breaks". The situation also permitted a measure of the rate of object selection. Excluding the selections after a "break", the time for each response ranged from 1.4 to 2.9 sec, with the frontals taking significantly longer to choose ( $P=0.05$ , Mann-Whitney). Finally, it was quite evident during the course of testing that the frontal animals took more "breaks" than non-frontals, and computation shows that they took a mean of 29.7 "breaks" over all trials, while non-frontals took a mean of 8.0 ( $P=0.001$ , Mann-Whitney).

Table 2. MEDIAN PERCENTAGES OF STEREOTYPED SELECTIONS

	Frontals $n=7$	Infero- temporals $n=5$	Normals $n=6$	Non- frontals $n=11$	$P$ Frontals versus non-frontals (1 tail test)
Complete analysis	11	77	55	66	$<0.025$
Between "breaks" analysis	$n=6$ 38.5	$n=2$ 77.5	$n=4$ 55	$n=6$ 60.5	0.03

Our results therefore indicate that frontal animals show less stereotypy (more randomness) in selecting stimuli where no reinforcement contingency is placed on their successive selections. Furthermore, the frontals interrupt their selections much more frequently, but the greater degree of randomness cannot be accounted for in this way. Finally, their rate of stimulus selection is lower than that of controls, but it is not possible in our situation to determine to what extent the decrease in rate is a direct result of the more random pattern of selection (for this involves more successive choices of widely separated stimuli).

A number of previous investigations have demonstrated that patterns of response by frontal monkeys are abnormal, but all of these required that the animal store information from trial to trial in order to maximize reinforcement<sup>6-8</sup>, and therefore it is difficult to disentangle the possible effects of alterations in memory mechanisms from such response patterns. Our results clearly reinforce the conclusion that frontals are less systematic in making successive responses<sup>9</sup>, even when no specific reinforcement contingency exists, but the suggestion that such increased randomness is due to frontal "hyperreactivity to environmental fluctuations" is not supported by our analysis, which shows that the frontal pattern was the

same whether "breaks" were considered or not. On the other hand, our results are in conflict with the hypothesis that frontals are more prone to stereotypy than control animals<sup>6</sup>.

There seems to be increasing evidence that frontal animals sample stimuli quantitatively and qualitatively differently from control animals. Thus, frontal monkeys have been shown to take briefer "glimpses" in a Butler Box situation<sup>10</sup>. Frontals make more errors, relative to controls, as the number of stimuli is increased in a non-delayed matching from sample situation<sup>11</sup>. Novel stimuli are given priority by frontals<sup>6,7,11</sup>. The characterization of the frontal defect in terms of an alteration in "flexible noticing order" would appear to encompass much the same type of attentional change as we indicate here<sup>7</sup>. The question which remains is whether such an attentional defect could account for the classical delayed response impairment. Some evidence that it could do so is provided by the observation that human delayed alternation performance is significantly impaired directly as a function of the number of irrelevant stimulus inputs during the delay period<sup>12</sup>, as well as the finding that delayed response performance of frontal monkeys is much improved by a drug which appears to interfere with perceptual performance in normal monkeys<sup>13</sup>.

We thank Miss Violet Cane, who formulated the statistical analysis.

## Earth Oscillations and the Earth's Interior

by

K. E. BULLEN  
R. A. W. HADDON

Department of Applied Mathematics,  
University of Sydney,  
Australia

Using data on spheroidal and torsional Earth oscillations, and taking account of the revised value of the Earth's moment of inertia, the variation of density and elasticity in the Earth has been re-examined. The most important among several new conclusions are that the radius of the core needs increasing by about 15 km and that a much reduced density gradient is required in the upper mantle.

THIS article reports some preliminary results on an extended revision we have been carrying out on values of the density  $\rho$ , incompressibility  $k$  and rigidity  $\mu$  as functions of depth in the Earth's interior. The revision takes account of the recently revised value<sup>1</sup>, from 0.3335 to 0.3309, of the coefficient  $\gamma$ , where  $\gamma = I/Ma^2$  and  $I$ ,  $M$  and  $a$  are the moment of inertia, mass and radius of the Earth respectively. It also takes account of observations of spheroidal and torsional Earth oscillations and evidence similar to that used in constructing Earth models of the types *A* and *B* (ref. 2).

The work has reached the stage where we can state some new conclusions. One of the conclusions (on the reduced density gradient in the outermost 400 km of the Earth) appears to be roughly in accord with a conclusion of Pekeris<sup>3</sup> whose paper reached us while we were preparing this article. Our approach differs from his, however, in significant respects and has led us to further conclusions not in his paper. (See also Toksöz and Anderson<sup>4</sup>.) Sections of an analysis by Landisman, Satō and Nafe<sup>5</sup> have proved useful in our investigation, though our main conclusions differ considerably from theirs.

We have sought to fit the oscillation data by starting from the Earth Model  $A'$  (ref. 2), corrected to fit the revised value of  $y$ , and have introduced a limited number of adjustable parameters which we have allowed to vary within what we would regard as plausible ranges. We have assumed that the Williamson-Adams equation<sup>2</sup> sets an approximate lower bound to the density gradient below, but not above, 1,000 km depth. Our procedures will be discussed in detail in a later publication.

After trial and error, we confined the parameters to the following three: the radius  $R$  of the core and the densities  $\rho_2$  and  $\rho_3$  just above and just below the boundary (at 413 km depth) between the regions  $B$  and  $C$  of model  $A'$ . In model  $A'$ ,  $R=3,473$  km and  $\rho_2=\rho_3=3.64$  g/cm<sup>3</sup>. Varying  $\rho_2$  meant changing the density gradient (which we kept constant) and so departing from the Williamson-Adams equation, in the region  $B$ . In all other respects, including initially the use of the Jeffreys values<sup>6</sup> of the  $P$  and  $S$  seismic velocities  $\alpha$  and  $\beta$ , we adhered to the procedures originally used in constructing model  $A'$ .

The parameter  $R$  was included for two reasons. First, a preliminary inspection had indicated that increasing  $R$  would act towards bringing the calculated periods for the lower-mode spheroidal observations into line with the observations. Secondly, evidence conveyed to us in 1964 by Sacks<sup>7</sup> added some physical plausibility to the notion of a larger core. Independent seismic evidence which points the same way has been presented by some other authors, for example, Kogan, Carder<sup>8</sup>. After our work had begun, Dorman, Ewing and Alsop<sup>9</sup> published details of an Earth model with  $R > 3,473$  km, but their oscillation calculations assumed the old value of  $y$ . Our procedure also differs from theirs in further respects.

Our selection of  $\rho_2$  and  $\rho_3$  as parameters was in part conventional. Early results from our calculations showed that the mean density in the region  $B$  of model  $A'$  has to be reduced to fit the oscillation data. Reducing the model  $A'$  value, 3.32 g/cm<sup>3</sup>, of the density  $\rho_1$  just below the crust would, however, run counter to current evidence<sup>10,11</sup>. Thus our preference was for taking  $\rho_2$  (or, equivalently, the density gradient in the region  $B$ ) rather than  $\rho_1$  as a parameter. The parameter  $\rho_3$  was introduced to provide further flexibility in the simplest way. We are not suggesting that there is necessarily a sharp change of property near 413 km depth or a first-order discontinuity in density anywhere inside the Earth's upper mantle. Our parametric representation for changes in the upper mantle is taken solely for convenience in a first approximation to corrections to model  $A'$ . It transpires, incidentally, that  $\rho_2=\rho_3$  in one of our better models, details of which are given below.

We have computed oscillation periods  $T$  for a considerable number of models with different  $R$ ,  $\rho_2$  and  $\rho_3$ . So far, we have concentrated mainly on fitting the observed  $T$  for fundamental spheroidal oscillations of order  $n$  up to 24, for fundamental torsional oscillations for  $n$  up to 18, and for a number of overtones. Our best models to date give nearly complete agreement with the observed  $T$  for these oscillations. For spheroidal oscillations with  $n > 16$ , the agreement is significantly better than in the results of Landisman *et al.*<sup>5</sup>, but can be slightly improved for  $n$  between 24 and 48 (the highest  $n$  for which we have computed values of  $T$ ). We expect to improve this agreement in a second approximation where further parametric adjustments will be made in the upper mantle.

A selection of the conclusions which seem to us fairly well established and of special interest to the broad problems of the Earth's interior are now reviewed.

If it is agreed to reject the zero density gradient in the lower mantle of Landisman *et al.*<sup>5</sup> as implausible, then there seems no easy escape from the necessity for a larger core radius. Our calculations favour an increase of 10–15 km. Any smaller increase would seem to us to entail greater departures from the Jeffreys (or Gutenberg)

velocities than seem likely. It seems possible that the oscillation data for the Earth will enable fairly close bounds to be set to the core radius independently of methods used in the past. Our work indicates that it is improbable that  $R$  exceeds (about) 3,495 km. The density gradient for a considerable distance below the crust is appreciably less than would be consistent with an adiabatic temperature gradient. Our present best models give density gradients in the region  $B$  only 0.2–0.3 times that given by the Williamson-Adams<sup>2</sup> equation (compare Pekeris<sup>3</sup>). Whereas Landisman *et al.*<sup>5</sup> reduced the density gradient in the lower mantle, we have reduced it in a part of the Earth where a reduction seems much more plausible.

The essential formal calculations of Landisman *et al.* have incidentally been verified in our work. If the value 3,471 km assumed by them for  $R$  is retained, our calculations indicate that a large reduction in the density gradient in the lower mantle is required. We would stress that our success in fitting the oscillation data, along with the revised  $y$ , comes about as a conjunction of two key features in our results: the increased core radius and the reduced density gradient in the region  $B$ . The reduced density gradient indicated in the upper mantle supplies important evidence on temperature gradients (compare Pekeris<sup>3</sup>).

Contrary to what a number of authors had regarded as well established, we find that the spheroidal data do not favour the Gutenberg velocities<sup>12</sup> in the upper mantle rather than the Jeffreys. When the optimum agreement with the spheroidal oscillations for  $n \leq 24$  is achieved using the Jeffreys velocities, we find, however, discrepancies (a little greater than the standard deviations) with the lower-mode torsional observations, discrepancies which cannot be fully removed by any adjustment in density that we would regard as plausible. The overall observational evidence (spheroidal and torsional) thus supports the conclusion of others that the values of  $\beta$  (but not  $\alpha$ ) are smaller than the Jeffreys values in the region  $B$ . We have yet to ascertain whether our approach will lead to definitive evidence on a "low velocity layer" for  $S$  in the upper mantle. The indicated reductions in  $\beta$ , and thus also  $\mu$ , inside the upper mantle are consistent with our other conclusions. They agree with the reduced density gradient in implying a comparatively high temperature gradient below the crust. They also add some plausibility to the adoption of a larger core radius, the previous estimate of which rests considerably on seismic  $ScS$  observations and so depends on assumed  $S$  velocities in the upper mantle.

The following values of  $\rho$ ,  $k$  and  $\mu$  apply to one of our best models (Table 1). Values in brackets give the changes in density from the original model  $A'$  values.

Table 1

Depth (km)	Density $\rho$ (g/cm <sup>3</sup> )	Incompressibility $k$ (10 <sup>12</sup> dyn/cm <sup>2</sup> )	Rigidity $\mu$ (10 <sup>12</sup> dyn/cm <sup>2</sup> )
33	3.32 (+0.00)	1.14 (−0.02)	0.62 (−0.01)
413	3.42 (−0.22)	1.61 (−0.12)	0.83 (−0.07)
1,000	4.65 (+0.00)	3.53 (−0.01)	1.86 (−0.02)
2,883	5.68 (+0.02)	6.48 (+0.01)	3.01 (+0.01)
2,900	9.80 (+0.1)	6.53 (+0.1)	0.0
4,983	11.90 (+0.0)	13.09 (0.0)	0.0
6,371	12.22 (+0.0)	(a = 11.36 km/sec)	

The density values of this model differ remarkably little from those in the original model  $A'$ , the only sizable changes being in the neighbourhood of the depth 413 km. So far as  $\rho$  is concerned, agreement with the oscillation data and the revised  $y$  is largely achieved by a simple transfer of mass from the upper mantle to the core. It would appear that the corrections needed to the original model  $A'$  are much less drastic than those inferred by Landisman *et al.*, and are largely confined to the upper mantle and the vicinity of the mantle-core boundary.

The above model is not final, and we hope to be able to refine it by taking further account of higher-mode oscillations, as well as of Rayleigh and Love wave observations; but we think that the conclusions listed here will survive our further calculations.

The behaviour of  $k$  at the mantle-core boundary of our model is interesting. Whereas the change  $\Delta k$  in  $k$  at the boundary was negative in the original  $A$ -type models,  $\Delta k$  is now positive, thus agreeing better with the indications of finite-strain theory. The change  $\Delta k$  in the model is also very small (less than 1 per cent), and gives remarkably close agreement with earlier assumptions<sup>13</sup> on compressibility in the Earth's deep interior.

In the second approximation, we propose to take account of additional detail in the upper mantle, evidence relating to the region  $D''$  (ref. 2), and recent work on the lower core<sup>14</sup>.

## Gravity Shock Waves and Stratification in the Upper Atmosphere

by

D. LAYZER

Harvard College Observatory,  
Cambridge, Massachusetts

Rocket measurements have produced direct evidence of small-scale fluctuations of wind speed and ionization, and observations show that these fluctuations are related. The fluctuations in wind speed are accounted for by the propagation of a novel form of shock wave in the atmosphere, and fluctuations of ionization such as sporadic E phenomena are then accounted for by the presence of metallic ions.

It has been known for many years that in middle latitudes the electron density does not in general vary smoothly with height between 90 and 125 km. Profiles of electron density measured with the help of electrostatic probes<sup>1</sup> and radio transmitters<sup>2,3</sup> mounted on rockets show narrow steep-sided peaks and sharp ledges. The vertical logarithmic gradient of electron density ( $d \log N/dz$ ) at the edge of a thin overdense layer sometimes exceeds  $100 \text{ m}^{-1}$ . Simple layers are typically about 1 km thick; thicker layers usually have two peaks. The enhancement of electron density in a thin layer relative to the background varies from a few per cent to an increase of three-fold or more during the day and ten or more at night. The most dense layers and those with the steepest gradients give rise to various sporadic E phenomena at very high frequency, such as long distance propagation of low-band television.

A recent study of winds in the upper atmosphere at latitude  $38^\circ \text{ N}$ . (Bedinger, J. F., Knaflitz, H., Manring, E., and Layzer, D., to be published) has shown that between 85 and 135 km the horizontal wind profile is invariably characterized by a well defined small scale structure. A typical hodograph of the horizontal wind in this height range is shown in Fig. 1. It consists of smooth arcs joined at sharp corners (which mark narrow layers, often less than 100 m in width) where the vertical gradient of the horizontal wind—but not the horizontal wind itself—changes abruptly.

On several occasions during the past 4 years horizontal winds and electron densities have been measured along similar rocket trajectories at nearly the same time<sup>4,5</sup>. An examination of a few early records suggested that narrow ionization peaks usually coincided with corners of the hodograph of horizontal winds<sup>6</sup>. This conclusion was confirmed by a subsequent study of a larger body of data

which included measurements of horizontal winds and ionization density along the same rocket trajectory<sup>4</sup>. The present communication suggests a physical interpretation

Fig. 1. Hodograph of the horizontal wind between 80 and 145 km, derived from multi-station photography of a sodium vapour trail on September 16, 1961. The horizontal wind is represented by a vector drawn from the centre of the figure (marked by a +). Between 80 and 120 km, 1-km height intervals are indicated; above 120 km, 5-km height intervals. The velocity scale, in m/sec, is indicated along the north-south axis.

of the small scale structure of the horizontal wind profile which accounts qualitatively for the accompanying small scale structure of the ionization profile.

To a first approximation, we may regard the narrow layers represented by corners in the hodograph of horizontal winds as surfaces of discontinuity. Such surfaces are of two types: those at which one or more components of the velocity are discontinuous (strong discontinuities); and those at which the velocity itself is continuous but one of its derivatives is discontinuous (weak or gradient discontinuities). Unlike strong discontinuities, weak discontinuities cannot arise spontaneously, but must be produced by some kind of singularity in the initial or boundary conditions of the flow. Because the surfaces under consideration do not appear to be associated with singularities in the boundary or initial conditions, they are presumably strong discontinuities—that is, shocks or contact discontinuities. The observation that the horizontal component of the velocity is continuous rules out contact discontinuities, which, moreover, are known to be unstable. Thus by elimination we arrived at the conclusion that the surfaces must be shock fronts, that is, surfaces at which the normal component of the velocity changes discontinuously.

The shocks cannot be ordinary compression shocks, however, as: (a) they move much too slowly; and (b) the observational evidence indicates that the winds in this region can only be interpreted as highly non-linear oscillations in the gravitational (rather than the compressional) mode. The gravitational mode is characterized by predominantly horizontal winds, small pressure fluctuations, and opposite vertical directions of phase and energy propagation. The surfaces of discontinuity under discussion are presumably related to gravity waves in the same way that compression shocks are related to compression (acoustic) waves. Observational evidence suggests that wave energy propagating upward is partially reflected at these surfaces.

A proper theory of gravity shocks (as they will be called here) would describe the growth of a surface of discontinuity in an initially linear gravity wave as it propagates upward. Such a theory has not yet been given. We shall adopt the working hypothesis that a discontinuity does develop. From the laws of conservation of mass, momentum and energy we can then derive a simple generalization of the Rankine-Hugoniot relations that describes gravity shocks as well as compression shocks.

Let  $\tilde{p}$  denote the dynamic contribution to the pressure

$$\tilde{p} = p - \int_z^\infty g \rho dz \quad (1)$$

where  $g$  denotes the acceleration of gravity and  $\rho$  the density. For simplicity we use the relation  $p = (\gamma - 1)\rho\varepsilon$ , valid for a perfect gas, where  $\gamma$  is the ratio of specific heats and  $\varepsilon$  is the density of the internal energy. We further neglect the accession of heat by gas moving through the front, and assume that the front is stationary with respect to the surface of the Earth. Finally, we assume that the thickness of the front,  $h$ , is sufficiently small that time derivatives (including the Coriolis contribution) can be neglected in comparison with vertical gradients. Then integration of the conservation relations across the front yields the three jump conditions

$$[\rho u_z]_1^2 = 0 \quad (2)$$

$$[\rho u_z^2 + \tilde{p}]_1^2 = 0 \quad (3)$$

$$\left[ \frac{1}{2} u^2 + \frac{\gamma}{\gamma - 1} \frac{p}{\rho} + gz \right]_1^2 = 0 \quad (4)$$

where  $u^2 = u_x^2 + u_y^2 + u_z^2$  and the indices 1 and 2

designate levels immediately below and above the front. From these equations and the continuity of the horizontal velocity components (which makes it possible to replace  $u^2$  by  $u_z^2$  in equation (4)), we can derive the formulae

$$\frac{u_{iz}^2}{c_i^2} = \frac{1 \mp \frac{gh\bar{\rho}}{p_i} \pm \frac{\gamma+1}{2\gamma} \frac{\Delta\tilde{p}}{p_i}}{1 + \gamma\eta \left( 1 - \frac{\gamma-1}{\gamma} \frac{\rho_i}{\bar{\rho}} \right)} \quad (5)$$

where the upper sign is to be used with  $i = 1$ , the lower sign with  $i = 2$ . In these equations

$$\Delta\tilde{p} \equiv \tilde{p}_2 - \tilde{p}_1, \int_{z_1}^{z_2} \rho dz \equiv \bar{\rho}h, c_i^2 \equiv \frac{\gamma p_i}{\bar{\rho}},$$

$$\eta \equiv -gh\bar{\rho}/\Delta\tilde{p} \quad (6)$$

The dimensionless number  $\eta$  is the ratio between the static and the dynamic contributions to the pressure jump. When  $|\eta| \ll 1$ , equation (5) describes a compression shock the structure of which is slightly modified by the effects of buoyancy. If  $|\eta| \gg 1$ , it follows from equation (5) that  $\eta$  must be positive, and hence  $\Delta\tilde{p}$  must be negative. If  $\eta \gg 1$  the equations describe a gravity shock. In this case they reduce to

$$\frac{u_{iz}^2}{c_i^2} \simeq \eta^{-1} \frac{1 \mp gh\bar{\rho}/p_i}{\gamma - (\gamma-1)\rho_i/\bar{\rho}} + O(\eta^{-2}) \quad (7)$$

Thus  $|u_z| \ll c$ , in agreement with observation. Measurements of vertical winds suggest that  $1 \lesssim |u_z| \lesssim 3 \text{ msec}^{-1}$ , so that  $10^4 \lesssim \eta \lesssim 10^5$ .

It follows from equation (2) that  $u_{1z}$  and  $u_{2z}$  have the same sign, and from equation (3) and from the inequality  $\Delta\tilde{p} < 0$  that  $|u_{2z}| > |u_{1z}|$ . Thus from equation (1)  $\rho_2 < \rho_1$ . From equations (2), (3) and (7) we obtain the relations

$$\frac{\Delta u_z}{u_z} = -\frac{\Delta\tilde{p}}{p_2} = \frac{gh\left(\bar{\rho} - \frac{\gamma-1}{\gamma}\rho_1\right)}{p_2} \equiv \frac{h}{H_2} \quad (8)$$

where  $H_2$  is a length closely comparable to the scale height. For a layer 1 km thick,  $\Delta\rho/\rho \simeq 0.1$ .

Next we consider the ionization profile. The equation of continuity for the electrons in a frame of reference which moves with the surface of discontinuity is

$$\frac{\partial N}{\partial t} + \frac{\partial(wN)}{\partial z} = q - r + \nabla \cdot (D\nabla N) \quad (9)$$

where  $N$  is the electron density,  $w$  is the vertical drift speed of neutral ionization,  $q$  is the rate of electron production,  $r$  is the rate of electron loss, and  $D$  is the electron diffusion coefficient. In middle latitudes and in the height range 90–125 km,  $w$  is approximately given by<sup>8-10</sup>

$$w = a_x(u_x - u_{0x}) + a_y(u_y - u_{0y}) + a_z u_z \quad (10)$$

where

$$u_{0x} = -E_y^{\text{pol}}/B_z, u_{0y} = E_x^{\text{pol}}/B_z \quad (11)$$

If the ionized component consists of electrons and positive ions,

$$a_x = -\frac{r^2}{r^2 + 1} \cos \chi \sin \chi, a_y = -\frac{r}{r^2 + 1} \cos \chi \quad (12)$$

Here  $E^{\text{pol}}$  denotes the electric polarization field, a slowly varying but in general unknown function of height;  $B_z$

denotes the vertical component of the Earth's magnetic field,  $\chi$  denotes the magnetic dip angle, and  $r$  denotes the ratio  $\omega_i/v_i$  between the gyro-magnetic and collision frequencies of the ions. The ratio  $r$  varies with height approximately like  $\rho^{-1}$ . At 100 km,  $r \simeq 1/10$ , while at 120 km  $r \simeq 1$ . Because in middle latitudes  $\sin \chi \simeq 1$ ,  $a_x$  is an order of magnitude smaller than  $a_y$  at 100 km but is comparable with  $a_y$  at 120 km.

In a layer where  $u_z$  and  $\rho$  change abruptly,  $w$  also changes abruptly. For appropriate values of the effective horizontal velocity components  $(u_x - u_{0x})$  and  $(u_y - u_{0y})$ , it can happen that  $w_1 > 0$  and  $w_2 < 0$ , so that ionization is drifting into the layer both from above and from below. In these circumstances, a dense layer can be built up. In less favourable circumstances,  $w_1$  and  $w_2$  have the same sign, so that only a small change in the ionization profile can occur. Thus the present theory predicts that conspicuous peaks in the ionization profile will coincide with some, but not all, layers marked by corners of the horizontal wind hodograph. It also predicts that the width of a simple (that is, single-peaked) ionization layer should not depend strongly on the density of the layer. Both predictions agree with experiment. The occasional occurrence of ionization peaks at levels that do not coincide with corners of the hodographs of the horizontal wind (three cases out of seventeen in the material studied in ref. 5) could be explained in either of two ways: (a) the vertical gradient of the horizontal wind could conceivably undergo a small jump at a surface where the vertical wind undergoes a large jump; (b) dense layers of ionization may be expected to persist for a certain period after the wind configurations that gave rise to them have disappeared.

On many of the hodographs of horizontal wind there occur pairs of sharp corners with vertical separations of only 2 or 3 km. If ionization is drifting into the upper layer of such a pair from above and into the lower layer from below, a double-peaked feature will result. If  $w \simeq 0$  at the two inner surfaces, the two peaks will be well separated; otherwise the region between them will be more or less filled in. Because the vertical drift velocity can be written in the form  $w = A\rho^{-1} + B\rho^{-2}$ , where  $A$ ,  $B$  are slowly varying functions of height, and as  $\Delta\rho < 0$  in each layer, a pair of closely spaced layers always constitutes a more effective ion trap than a single layer. The observational evidence does, in fact, indicate that thick layers usually have a well defined double peaked structure. Occasionally they resolve into a pair of distinct layers with sharp inner edges.

If the net flux of ionization into a layer is positive, ionization will accumulate in it until the inward flux is balanced by recombination losses. In the region of the atmosphere under consideration the principal ionized constituents are probably oxygen and nitric oxide. During the day the recombination times of these ions are of the order of  $10^3$  sec. Such times are too short to allow substantial local increases in the electron density to occur because  $\Delta w$  is of the order of 1 m/sec at most. Moreover, the fact that dense daytime layers of ionization are not associated with a marked reduction of the background electron density indicates that redistribution of the principal ionized constituents is not the process by which dense layers are formed<sup>5</sup>. These considerations suggest that the ions responsible for narrow peaks in the ionization profile make a relatively minor contribution to the total number of ions in a column of unit cross-section—at least during the day—but have long lifetimes. Atomic metallic ions, such as sodium, magnesium and iron, the lifetimes of which are measured in days, satisfy these conditions. Because sharp corners in the hodographs of horizontal wind appear to persist for many hours, the long-lived metallic ions may be expected to collect in a few thin layers. Only the densest of these would be conspicuous during the day, because of the high background density of ionization. But at night, with the gradual subsidence

of the background associated with short-lived molecular ions, the underlying spiny structure of thin layers of metallic ions would gradually emerge. This picture is in qualitative agreement with observation. Independent evidence in support of the view that dense layers are made up largely of atomic metallic ions comes from recent mass-spectrometer measurements (ref. 11, and Johnson, C. Y., personal communication).

A conspicuous feature of sporadic  $E$  layers is their patchy structure. A typical sporadic  $E$  layer is a few hundred kilometres in diameter, but its vertical critical frequency  $fE_s$  (the maximum frequency observed to be reflected at vertical incidence) varies considerably over the surface. The horizontal scale of the variation is a few tens of kilometres. The present hypothesis for the formation of dense layers does not lead one to expect substantial local variations of the total number of electrons in a dense layer. On the other hand, the vertical gradient of electron density at the lower edge of a layer may be expected to exhibit large local fluctuations, because it is an extremely sensitive function of the drift speed  $w_1$  when  $w_1$  is close to 0 (in the absence of diffusion,  $dN/dz \rightarrow \infty$  as  $w_1 \rightarrow 0$ ). Because the radio wavelengths in question are comparable with observed values of  $(d \log N/dz)^{-1}$  at the edges of dense layers, small local variations in the winds could give rise to substantial changes in reflectivity at these wavelengths.

The present hypothesis for the formation of narrow, dense layers of ionization may be compared with the wind-shear theory<sup>12-14</sup>, which is also based on equations (9) and (10). In the wind-shear theory  $a_x$ ,  $a_y$  and  $u_z$  in equation (10) are regarded as slowly varying functions of height, and the formation of narrow, dense layers of ionization is attributed to large vertical gradients of the effective components of horizontal wind  $(u_x - u_{0x})$  and  $(u_y - u_{0y})$ . Calculations based on observed profiles of horizontal wind, however, indicate that vertical gradients of the horizontal wind are responsible for comparatively broad and shallow features of the ionization profile, and not—except, perhaps, in isolated instances—for narrow layers of dense ionization<sup>5</sup>.

The possible importance of long-lived ions was pointed out, in the context of the wind-shear theory, by Whitehead<sup>15</sup> and Axford<sup>16</sup> in reply to a criticism of the original, single-ion form of this theory<sup>5</sup>, and also by Cuchet<sup>17</sup>. The possibility that sporadic  $E$  layers might be made up of meteoric ions was explicitly discussed at a seminar on sporadic  $E$  held at Estes Park, Colorado, in the summer of 1965.

I thank Dr. E. R. Constantinides, Professor C. C. Lin and Dr. E. K. Smith for valuable comments and suggestions. This work was supported in part by the U.S. National Aeronautics and Space Administration.

## LETTERS TO THE EDITOR

## ASTRONOMY

Hydrogen Recombination Lines 126 $\alpha$  and 166 $\alpha$  observed in Galactic HII Regions

Using the Parkes radiotelescope, we have searched the Southern Milky Way for the 126 $\alpha$  hydrogen recombination line of rest frequency 3248.713 Mc/s. (The notation  $n\alpha$  indicates a transition from the level of quantum number  $(n+1)$  to level  $n$ ;  $n\beta$  indicates a transition from  $(n+2)$  to  $n$ .) Nineteen sources were inspected and the line was detected in fifteen, all of which were well known HII regions. The nebulae<sup>1</sup> were

Orion Nebula	RCW 57	NGC 6334
IC 434	RCW 74	NGC 6357
RCW 38	1808-51	M 17
$\eta$ Carinae (two positions)	1617-50	W 49
	1618-49	W 51

Four neighbouring points were checked in the Orion Nebula and M 17 to establish that the maximum line intensity corresponded to the maximum continuum temperature.

A probable detection was made in the galactic centre source at  $l_{II} = 40'$ ,  $b_{II} = -2'$ . No detections were made in the two non-thermal sources, Sagittarius A and the Crab Nebula. The extra-galactic source, 30 Doradus in the Large Magellanic Cloud, gave a negative result, possibly because the sensitivity was not great enough.

The three most intense HII regions, Orion Nebula, M 17 and RCW 38, were later observed for the 166 $\alpha$  line, with a rest frequency 1424.736 Mc/s.

Table 1 shows details relating to the three sources of: (i)  $T_L$ , the peak line intensity in terms of aerial temperature; (ii) the ratio  $T_L/T_C$ , where  $T_C$  is the corresponding aerial temperature in the continuum; (iii)  $\Delta\nu$ , the half-intensity width of the line, corrected for broadening with 37 kc/s filters; and (iv) the central line radial velocities (referred to the local standard of rest).

Table 1. SUMMARY OF OBSERVATIONS OF HYDROGEN RECOMBINATION LINES 126 $\alpha$ , 166 $\alpha$

Source	Line	$T_L$ (° K)	$T_L/T_C$ (per cent)	$\Delta\nu$ (kc/s)	Radial velocity (km/s)
Orion Nebula	126 $\alpha$	$6.4 \pm 0.1$	3.5	$430 \pm 10$	-2
	166 $\alpha$	$1.9 \pm 0.1$	0.8	$215 \pm 10$	0
M 17	126 $\alpha$	$5.7 \pm 0.1$	3.1	$388 \pm 10$	+20
	166 $\alpha$	$3.0 \pm 0.1$	1.05	$203 \pm 20$	+20
RCW 38	126 $\alpha$	$2.4 \pm 0.1$	2.5	$398 \pm 15$	+4
	166 $\alpha$	$1.2 \pm 0.1$	1.05	$156 \pm 20$	+8

Palmer and Zuckerman<sup>2</sup> have detected the 166 $\alpha$  line in only M 17. Their values of  $T_L/T_C$  and  $\Delta\nu$  are  $0.9 \pm 0.2$  per cent and  $183 \pm 60$  kc/s when corrections are made for their 80 kc/s bandwidth.

Recently, we have considered<sup>3</sup> the ratio of the peak intensities of the 126 $\alpha$  line to the  $\beta$  lines, 159 $\beta$  and 158 $\beta$ , at nearby frequencies, 3211.245 and 3272.219 Mc/s, respectively. In the source M 17, the ratio  $I(158\beta)/I(126\alpha)$  of  $0.22 \pm 0.04$  was close to the theoretical value 0.224 derived from formulae set down by Kardashev<sup>4</sup>. In the Orion Nebula, however, the ratio was considerably lower:  $0.13 \pm 0.03$ . Without observations at lower frequency to give bandwidths near 158 $\alpha$  it was impossible to infer whether this resulted from departures from local thermodynamic equilibrium of the populations or to appreciable broadening of the energy levels involved in the 158 $\beta$ , 159 $\beta$  transitions (and the corresponding  $\alpha$  transitions) in the Orion Nebula. As the Bohr radius is proportional to the square of the principal quantum number, the 158, 159 levels will be more affected by electron and ion densities than levels near 126. It is well

known that the density is considerably higher in Orion than in M 17.

In Fig. 1,  $T_L/T_C$  and  $\Delta\nu$  have been plotted against frequency over the range of the present observations so that values for the 158 $\alpha$  line may be obtained by interpolation. The results for the 126 and 158  $\alpha$ -lines for the Orion Nebula may be compared with those for M 17. The 126 and 158  $\alpha$ -lines have been observed under similar conditions except for the increase in beamwidth from 6' arc to 14' arc.  $I(158\alpha)/I(126\alpha)$  is 0.31 for the Orion Nebula and 0.43 for M 17; that is, the Orion value is 0.73 of the M 17 value. The ratio  $I(158\beta)/I(126\alpha)$  for the two sources was 0.59. The small difference could be accommodated within the experimental errors.

Fig. 1. Recombination line half-width,  $\Delta\nu$  (broken lines), and the ratio of line intensity to continuum intensity,  $T_L/T_C$  (full lines), are plotted against frequency (in G c/s) over the range of the 166 $\alpha$  and 126 $\alpha$  lines for the HII nebulae.  $\square$ , Orion Nebula;  $\Delta$ , M 17;  $\circ$ , RCW 38.

On the other hand, the corresponding ratio of  $\Delta\nu$  for the two lines is effectively the same (0.96) for both sources, and thus broadening is inadequate to account for the intensity ratios.

We infer from the results that the populations at least for Orion are not in agreement with a Boltzmann distribution. The likelihood of such a situation has been discussed by Goldberg<sup>5</sup>.

### Variation of the Positional Angle of the Polarization Plane of Radiosources with Time

THE expansion of the volume in which relativistic particles, magnetic fields and ionized gases are contained must be accompanied by both a decrease of the flux density of the synchrotron radio-emission<sup>1</sup> and a change of its polarization parameters. If the radio-emission of such a source is linearly polarized and if the plane of polarization undergoes Faraday rotation  $\varphi_s$  within the source itself and Faraday rotation  $\varphi_g$  in the galactic interstellar medium<sup>2-4</sup>, then with a sufficiently rapid expansion of this source, the rate of change of the positional angle will be

$$\dot{\phi} = \dot{\varphi}_s + \dot{\varphi}_g \simeq 8.1 \times 10^5 \lambda^2 \frac{d}{dt} \int_0^R n_e H_r dr \quad (1)$$

But  $\varphi_s \gg \varphi_g$  in equation (1) so that the rotation at a distance of one radius of the source is assumed to be the characteristic Faraday rotation with the source. In the simplest model, the source will be transparent at wavelength  $\lambda$  and the non-uniform magnetic field will consist of quasi-uniform regions differing only in the direction of the field and growing with the source without change in relative size. Then if  $n_e \propto R^{-3}$  and  $H \propto R^{-2}$ , we obtain

$$\varphi_s = 8.1 \times 10^5 \lambda^2 \left(\frac{R_0}{R}\right)^6 \int_0^R (n_e H_r)_0 dr = \varphi_0 \left(\frac{R_0}{R}\right)^4; \quad (2a)$$

$$\frac{\dot{\phi}}{\varphi_s} = -4 \frac{\dot{R}}{R} \quad (2b)$$

If  $\dot{\phi}$ ,  $\varphi$  and  $\dot{R}/R$  are measured (the last by optical means), the rotation in the source and in the Galaxy can be individually determined. The equalities (2) can be considered only to be approximate, because they do not take into account differences in the physical parameters of the elements, their relative movements and the expansion anisotropy.

Let us compare (2b) with the rate of secular decrease of the flux density during the expansion. According to Shklovsky<sup>1</sup>  $\dot{S}/S = -2\gamma \dot{R}/R$ , where  $S \propto \lambda^\alpha$ ,  $\gamma = 2\alpha + 1$ . Here the absence of the injection of relativistic particles is assumed. Substituting from (2b), this can be written

$$\frac{\dot{\phi}/\varphi_s}{\dot{S}/S} = \frac{2}{\gamma} \quad (3)$$

The accuracy of (3) is limited by the previously mentioned assumptions except for the expansion anisotropy.

The approximations of  $\dot{\phi}$  from equation (3) indicate that this effect can probably be discovered in the course of several years. For Cassiopeia A,  $\dot{S}/S \simeq -1.1$  per cent/yr<sup>5-7</sup> at  $\alpha = 0.8$  (ref. 8). Boland *et al.*<sup>9</sup> have measured a small linear polarization of Cassiopeia A at a wavelength of 2.07 cm. Thus at the wavelength at which  $\varphi_s = 1$  rad it is probable that the variation of the positional angle will be  $\sim 0.5^\circ$ /yr. Contrary to the flux density, measurements made on the Earth's surfaces of the permanent positional angle are not subjected to atmospheric extinction at centimetre wavelengths. Because, for the Crab Nebula,  $\dot{R}/R = 10^{-3}$ /yr,  $\varphi \simeq 1$  rad at a wavelength of 21 cm<sup>10</sup> and  $\alpha = 0.25$  (ref. 8) we find that  $\dot{\phi} 0.25^\circ$ /yr and  $\dot{S}/S \leq 0.3$  per cent/yr. Such an estimate does not take into account the extent of the Faraday rotation or the expansion anisotropy of the Galaxy. Because of the presence of the regular magnetic field and the possible injection of the relativistic particles in the Crab Nebula the value for  $\dot{\phi}$  seems to be more reliable than that for  $\dot{S}/S$ .

Of particular interest are measurements of  $\dot{\phi}$  for radio-variable quasars. Given these values it would be possible to establish whether the linearly polarized radio-emission comes from the variable central nucleus of the quasar and, if so, to draw some conclusions about the mechanism involved in the generation of variable radio-emission.

If the mechanism were to be of the synchrotron type and if the radio variability were to be caused by the expansion of the region in which the radio-emission is generated (refs. 11-13), then in some cases the effect would be sufficiently large to be observed over a period of years. For example, if the Faraday rotation of the Galaxy, the opacity of the sources due to the synchrotron reabsorption and relativistic effects resulting from very fast expansion are not taken into account, the decrease of the flux density of 3C 345 during 1964-65 for 20 per cent/yr at a wavelength of 10.6 cm<sup>14</sup> corresponds to  $\leq 5^\circ$ /yr. Here I have taken values for the rotation of about 20 rad/m<sup>2</sup> (ref. 15) and  $\alpha = 0$ . Similarly, values for 3C 279 are  $\sim 28$  rads/m<sup>2</sup> for rotation (ref. 15) and  $\alpha = 0$  (ref. 16). Thus the increase of flux density for 6 per cent/yr during 1963-65 at a wavelength of 21.2 cm could be accompanied by the change of the positional angle  $\dot{\phi} \leq 9^\circ$ /yr.

## PLANETARY SCIENCE

### Equal Areas of Gondwana and Laurasia

IN a recent communication, Dietz and Sproll<sup>1</sup> have taken the contact between Gondwana and Laurasia as a line along the axis of the Persian Gulf continued through Iraq and Syria to meet the axis of the Mediterranean Sea. Geological evidence does not support this generalization.

Stoeklin (ref. 2, and in a paper presented at the International Colloquium on the Tectonics of the Alpine folded regions of Europe and Asia Minor, held in 1965 at Tiflis, U.S.S.R.) gave reasons for thinking that Arabia and Iran throughout the Palaeozoic era formed part of one stable platform created by Pre-Cambrian orogenies. In the Middle East it is not possible to identify margins for Gondwana and Laurasia in Palaeozoic times. Throughout the Mesozoic and Tertiary eras, however, the well marked Zagros thrust belt, which continues north-west into northern Iraq and Syria, is the geological choice for the northern margin of the Arabian shield. This is a mobile belt of eugeosynclinal type which has suffered two or more orogenies since Jurassic times. The rocks which outcrop in it are different in lithological type from those deposited in the Persian Gulf geosyncline, which subsided gradually during Mesozoic and Lower Tertiary times accumulating some 20,000 ft. of dominantly calcareous sediments which are essentially miogeosynclinal, folded by the Pliocene orogeny, which was most intense in the Zagros thrust belt. It is therefore necessary to place the contact between the shields at least as far north as

the inner Zagros thrust belt; the interpretation farther north-east is still geologically obscure.

Dietz and Sproll do not say where they have taken the contact of Gondwana and Laurasia farther east between the Persian Gulf and West Pakistan. There is clearly insufficient evidence to identify a northern margin to Gondwana in this area now, because it has either foundered beneath the sea or suffered a Cary spenochasm. But in Upper Cretaceous times we do know that the Zagros eugeosynclinal belt bent around into Oman to run south and south-east towards the Arabian Sea. It is logical to assume on geological grounds that this orogenic belt was connected in some way with the belt of Upper Cretaceous folding which runs north from Karachi: that this belt connects under the Arabian Sea with the Murray Ridge is unlikely to be pure coincidence.

The necessary change in the position of the Middle Eastern Gondwana and Laurasia contact adds about 700,000 km<sup>2</sup> to the former supercontinent at the expense of the latter, confirming that the apparent close similarity of the areas of the two supercontinents measured by Dietz and Sproll must be fortuitous, as they acknowledge.

### Particles in Volcanic Fume

THE relatively quiet outpouring of lava during many volcanic eruptions, such as those in Hawaii and Iceland, is accompanied by the emission of large quantities of fume. Almost nothing is known about the particles in such fume although numerous studies have been made of the gaseous composition<sup>1,2</sup>. At times in the Earth's history, for example during the eruptions that produced the Columbia Plateau in the United States, tremendous amounts of such particles must have been emitted into the atmosphere.

During 1965, Halemaumau (the main vent of Kilauea volcano in Hawaii) emitted large amounts of fume (Fig. 1). This is unusual for Kilauea except during an actual eruption and suggests that magma was very close to the surface. The odour of the fume was similar to that of sulphur dioxide. Scattered light from the fume in the crater was bluish, but as the fume rose it became white, suggesting that the particles were absorbing water vapour and enlarging as they rose.

Samples of the particles in this fume were collected in August, September and December of 1965. Both a 'Unico' multistage impactor and a filter composed of polystyrene fibres less than a micron in diameter were used. Fume was drawn through the impactor and filter with a 'Gelman' battery driven pump or a 'Uni-Jet' air sampler. Particles collected at the crater's edge with the impactor were entirely on the third and fourth stages, which at the flow-rates used collected particles which had mass median diameters of about 5 $\mu$  and 3 $\mu$  respectively, assuming that the particles had a density of 1 g/cm<sup>3</sup>. The particles were undoubtedly much smaller when first

Fig. 1. The appearance of Halemaumau in September 1965. The fuming crater is about one half mile across.

emitted from the vents. Almost no particles were collected on the impactor slides away from the crater.

Microscope examination of the impactor samples showed that they were agglomerated droplets that remained liquid at a relative humidity of 30 per cent, and consisted of supersaturated aqueous solutions of a crystalline solid. Tests with Nessler's reagent and with an aqueous solution of barium chloride showed that the solute contained ammonium and sulphate ions, respectively. The crystalline solute was tinged yellow but probably did not contain elemental sulphur since it was soluble in water and insoluble in carbon disulphide. Possibly some ferric ions were present. Testing with acidified aqueous silver nitrate solution failed to reveal the presence of any chlorine ions. The droplets absorbed water and grew in size when the impactor slide was placed on a moist chamber on the microscope stage.

Using the electron diffraction feature of an electron microscope, electron diffraction patterns were obtained for about thirty crystals of the solute from the impactor slides. All corresponded to ammonium sulphate; no sodium chloride or sulphur particles were found.

Particles collected on the fibre filter were examined with the electron microscope using a replica technique. Many of the particles (which, of course, were evaporated droplets) were in the size range 1–10 $\mu$  diameter. There were also large numbers of smaller particles.

Ammonia has not previously been reported in the fume from Kilauea although it is known to be emitted by other volcanoes<sup>3,4</sup>. Although these samples were handled with great care, the possibility that they were contaminated with atmospheric ammonia cannot be dismissed. Additional investigations of this kind, especially of the fume above molten lava, are needed to establish whether ammonium sulphate is indeed an important component of the fume of erupting volcanoes. If so, enormous amounts of ammonium sulphate must at times be emitted into the atmosphere by volcanic eruptions.

**Physical and Chemical Properties of Volcanic Glass Shards from Pozzuolana Ash, Thera Island, and from Upper and Lower Ash Layers in Eastern Mediterranean Deep Sea Sediments**

Two volcanic ash layers have been correlated in deep sea piston cores from the eastern Mediterranean<sup>1,2</sup>. The lower ash layer ( $n = 1.521$ ) occurs between late Würm carbonate sediment and originated in an eruption more than 25,000 years ago. The upper ash layer ( $n = 1.509$ ) occurs in postglacial carbonate sediment less than 5,000 yr old. Patterns of distribution indicate that both beds of volcanic ash originated in eruptions of Santorini (Aegean Sea).

During the Würm eruption of Santorini (Fig. 1), the bottom of much of the Eastern Mediterranean was covered by a layer of ash a few centimetres thick<sup>2</sup>. The lower ash ( $n = 1.521$ ) is spread out in an elongate pattern extending to the west and to the south-east. A further big eruption occurred during postglacial time (late Minoan I). It formed the present caldera of Santorini (83 km<sup>2</sup> in area) and deposited the pozzuolana ash which is 30 m thick. The ash covers the islands of Thera, Therasia and Aspronisi, which are remnants of the former volcanic cone. The upper ash layer ( $n = 1.509$ ) in deep sea sediments is distributed between the Aegean Sea and Egypt, decreasing in thickness toward the south-east<sup>2</sup>.

In the present study the physical and chemical properties of pozzuolana from Thera island and the upper and lower ash from deep sea sediments have been examined. This investigation indicates that the upper ash ( $n = 1.509$ ) from deep sea sediments and the pozzuolana from Thera island are identical in composition.

The sample of pozzuolana analysed was obtained to the south of Phira on Thera island and the samples of

upper and lower ash in deep sea sediments chemically analysed are from core V10-58 (Figs. 1 and 2)

The pozzuolana from Thera<sup>3</sup> and the lower and upper ash from deep sea sediments<sup>1,2</sup> are composed of about 97 per cent volcanic glass and 3 per cent minerals. The sample of pozzuolana examined in this study, however, was contaminated with a large amount of residual sand. The three samples were first boiled in a 20 per cent solution of hydrogen peroxide and sieved. The fraction in the range of size 0.177–0.062 mm was further examined. A solution of bromoform and alcohol (specific gravity = 2.65) was used for the separation of volcanic glass shards from heavy minerals. The light fraction was treated with a 15 per cent solution of hydrochloric acid to eliminate the possible presence of calcium carbonate or iron oxide, and was then passed through the Franz isodynamic separator. Maximum current obtained by the instrument was 1.5 amps. The remaining portion of heavy minerals as well as the glass shards which contained inclusions of minerals was separated at less than 0.8 amps. Plagioclase and quartz were separated at more than 1.4 amps. Thus, practically the total amount of pure volcanic glass shards from the original samples in the size fraction 0.177–0.062 mm was concentrated between about 0.8 and 1.4 amps. The magnetic properties of the volcanic glass in the three samples are shown in Fig. 3, and the pozzuolana and the upper ash (core V10-58) are nearly identical. There is a similarity between these two ash beds with regard to other physical properties (Table 1).

Mellis<sup>1</sup> pointed out that in all the *Albatross* cores in which the ash layers were found, the lower layer ( $n = 1.52$ ) was brownish grey and the upper layer ( $n = 1.51$ ) was light grey. Parker<sup>4</sup>, however, has constructed climatic curves based on the percentage of warm and cold foraminiferids for each *Albatross* core. She found that the

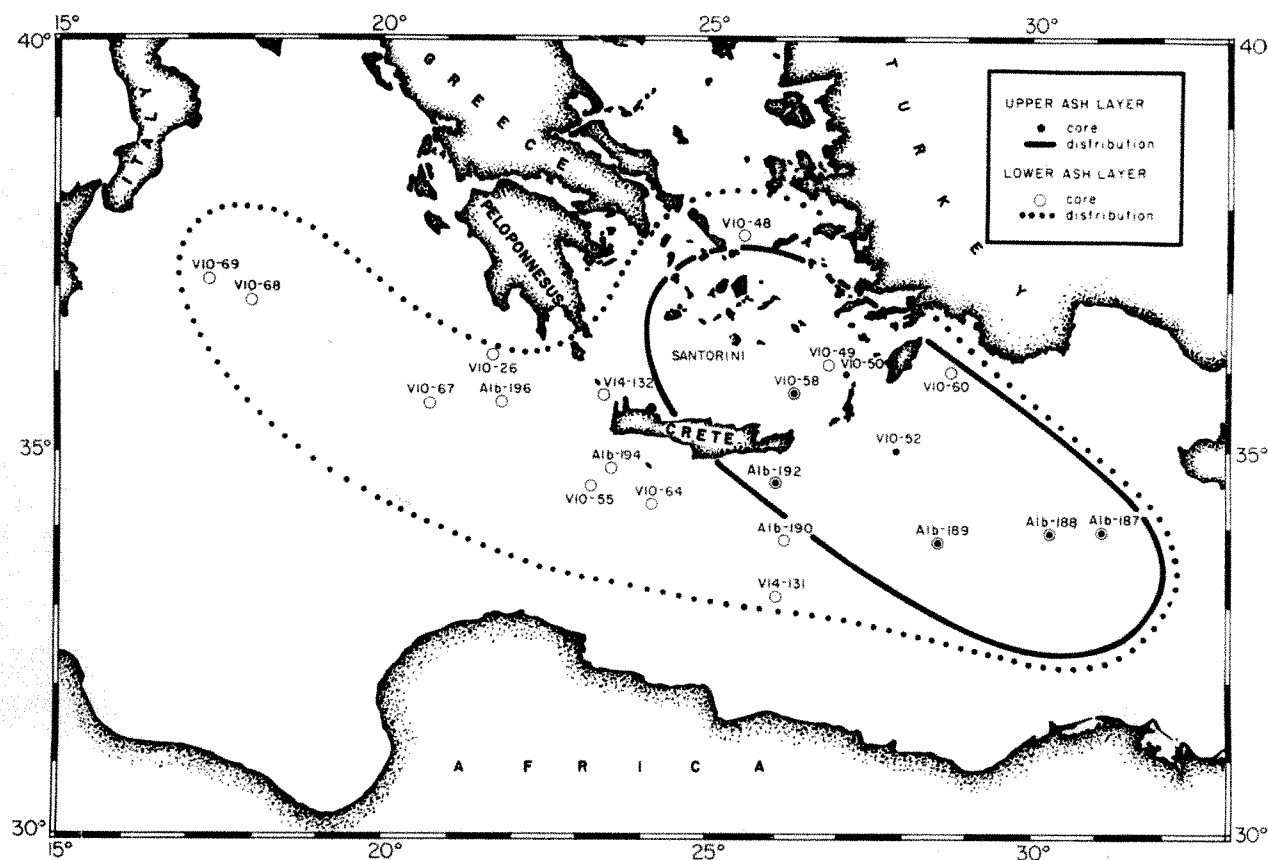

Fig. 1. Distribution of volcanic ash in eastern Mediterranean deep sea cores.

Fig. 2. Graphic logs of eastern Mediterranean deep sea cores containing volcanic ash layers.

lower ash layer occurred in the late Würm and the upper ash layer in postglacial sediments. This corresponds to the sequence found in *Vema* cores<sup>2</sup>. The only exception found by both Parker<sup>4</sup> and Olausson<sup>5</sup> represents cores *Alb* 187 and 188, where both lower and upper ash layers are interbedded with cold, presumably late Würm, foraminifera. We have compared samples of the upper and lower ash in cores *Alb* 187 and 188 provided by Dr. Mellis with ash layers in *Vema* cores. On the basis of their physical properties the upper and lower ash layers in these two cores correlate with the upper and lower ash

layers, respectively, from the *Vema* cores. This suggests some mixing or contamination in the foraminiferal records of these two cores. Fig. 1 shows that the pattern of the distribution of the upper ash layer originated in the post-glacial (Minoan) eruption of Santorini can be extended farther to the south-east if cores *Alb* 187 and 188 are included. During the late Würm eruption of Santorini, however, the prevailing high altitude winds were both north-westerly and easterly.

Pure volcanic glass from pozzuolana was first analysed chemically by Fouqué<sup>3</sup> (sample 1, Table 2). Washington<sup>6</sup> analysed a sample of pozzuolana which contained about 97 per cent volcanic glass and 3 per cent minerals (sample 2). Three samples of pure volcanic glass the physical properties of which were examined in this study were recently analysed by S. Imai of the Analytical Chemistry Research Institute, Tokyo.

Volcanic glass from pozzuolana (sample *Th*) and from the upper ash in core *VIO*-58 (sample *U*) show nearly identical chemical compositions. The volcanic glass from the Würm eruption (sample *L*) differs from the Minoan glass primarily in the ratio silica to alumina and in the percentage of potassium oxide.

The *Vema* sediment cores were collected by Professor Maurice Ewing. Professor O. Mellis provided samples of ash from the *Albatross* cores. The pozzuolana samples

## PHYSICS

### Interfering VLF Radio Signals observed on GBR-16.0 Kc/s Transmissions during November and December 1965

In May and June 1962, Rohan *et al.* observed unexplained sudden amplitude and phase changes on GBR signals at Salisbury, South Australia<sup>1</sup>. Allan reported similar observations made simultaneously at Lower Hutt, New Zealand<sup>2</sup>. He suspected interfering signals from a powerful transmitter in the vicinity of Australia and operating near 16.0 Kc/s\*. In April 1963, Allan recorded anomalies on the 18.0 Kc/s very low frequency transmissions emitted by NBA<sup>3</sup> and in 1964 Isted proposed an explanation of these "peculiar phenomena" in terms of antipodal signal interference and changes in propagation conditions over one or both great circle routes<sup>4</sup>.

Our NBA records of April 1963, taken at Deal (New Jersey), also show phase anomalies with times of observation which agree with the times given by Allen. The anomalies of April 12, 13 and 14 were almost unnoticeable, but the anomaly of April 16 was quite strong. If it was caused by an interfering signal, its frequency had an offset of approximately  $7 \times 10^{-7}$  and its amplitude at Deal could have been as large as 6 dB below that of the signal from NBA which is located only 3,500 km south of Deal.

This simultaneous observation of an anomaly at Lower Hutt and Deal strongly reduces the probability of an antipodal signal interference<sup>4</sup> because an antipodal NBA signal to Deal crosses 4,500 km of Antarctic and Greenland ice and has a path length ten times greater than that of the short-path signal.

Malfunction of the transmitter control circuit as a cause of the anomalies was dismissed by Allan because the British Post Office had allegedly found no evidence of an

\* Nominal value, actually emitted on UT-2 time scale.

anomaly on its May/June 1962 GBR records; also the U.S. National Bureau of Standards at Boulder found no NBA phase anomalies in April 1963 (ref. 3). The discrepancy between the Boulder and Deal records can be readily resolved by the fact that the Deal tracking station had a time constant which was probably five times shorter than that of the Boulder equipment—an important consideration with fast phase variations.

Simultaneous observation of numerous phase and amplitude anomalies on the 16.0 Kc/s GBR signal with practically identical equipment (servo time constant 50 sec) at eight widely separated locations in November and December 1965 confirms beyond doubt that the anomalies were caused by an interfering transmitter. Fig. 1 shows two typical interference records. Table 1 lists pertinent data. In all cases the anomalies were strongest at Tokyo, followed in general by those observed at Brisbane; Oslo II (a temporary aurora research site in the Arctic); Kiruna, Sweden; Tananarive, Malagasy; Beirut, Lebanon; Deal; and C. Rivadavia, Argentina. The interference always saturated the amplitude channels at Tokyo and (except in December 1965) at Brisbane, indicating an interference signal level of between 20 dB and more than 35 dB above the local GBR signal strength at Tokyo. The interferences, however, were often barely detectable at Deal and C. Rivadavia. All stations received GBR with tuned loop antennae.

The frequency of the interfering signal was on average either approximately  $10^{-7}$  parts above or  $10^{-7}$  parts below the highly stable GBR carrier frequency, and often changed by several parts in  $10^8$  during the few minutes of interference.

Fig. 1. Typical example of recorded GBR phase and amplitude interference during November 1965.

The possibilities of interference by signals with frequencies (a) equal to the image frequency of the involved receivers (2 Kc/s), and (b) corresponding to harmonics of the local synthesizer frequency, or (c) differing by the amount of the intermediate frequency value of the receiver (1 Kc/s), can all be discarded because the receiver systems involved have a rejection level of well above 50 dB for such signals (as verified by laboratory experiments).

The interfering signals during the 1965 period in question must consequently have originated from a transmitter located somewhere in East Asia. It could have been a transmitter with a frequency assignment close to

16.0 Kc/s<sup>5</sup> which inadvertently strayed off frequency during testing. Alternatively it could have been any transmitter there which for some reason experimented near 16.0 Kc/s<sup>5</sup>.

The interference always lasted only a few minutes and, as no one realized its true nature at the time, no effort was made at the time to obtain bearings on the interfering transmitter. Oslo II, however, monitored GBR from November 17 to 19, 1965, with two receivers, one fed from a bidirectional loop oriented 25° west of geographic north, the other from an omnidirectional whip. A comparison between the phase and amplitude patterns of the two receivers points to a location of the interfering transmitter somewhere between 100° E. and 140° E.

We computed for all eight receiving sites the field strengths,  $E$ , of GBR and the unknown interfering transmitter,  $X$ . We took the radiated power of both transmitters as 40 kW and selected fourteen locations for  $X$ , distributed between 75° E. and 165° E. longitude. Some locations coincided with listed very low frequency transmitters<sup>5</sup>, some were arbitrarily assumed.

For each of the fourteen locations of  $X$  and each of the eight receiving sites we calculated the difference  $\bar{D} = (E_{GBR} - E_X)_{CALCUL.} - \Delta E$ , averaged over five different epochs, between November 12 and 19, 1965.  $\Delta E$  is the difference of GBR and  $X$  field strengths derived from recorded interference phase patterns. We then calculated the standard deviations of the  $8\bar{D}$  values pertaining to each of the fourteen assumed  $X$  locations. These standard deviations had a minimum value for  $X$  locations within the area bounded by 32° N. and 55° N. latitudes, and 105° E. and 140° E. longitudes.

Very low frequency field strength calculations for such different paths are rather unreliable. The agreement between the locations of  $X$ , however, which were obtained by (a) the method of calculating standard deviations of  $\bar{D}$  values, (b) crude comparison of degrees of interference measured at the eight separate receiving stations, and (c) calculation of the bearing to  $X$  from one receiving site, is none the less rather startling.

The choice of the standard deviation of the  $\bar{D}$  values as a measure for the likelihood that  $X$  lies at a certain location eliminates to some degree the need to know the radiated power of  $X$  for calculating  $E_X$ . The average  $D$  value of the most probable  $X$  location should, however, be close to zero. Because under the given assumptions it turned out to be approximately 8 dB, it is necessary to assume a lower radiated power of GBR and/or a larger radiated power of  $X$ . These conditions could easily be met by reasoning that GBR was actually on keyed transmission (duty cycle less than 1), whereas  $X$  was probably on key-down operation (duty cycle equals 1) according to the nature of the interference.

Fig. 2 illustrates the distribution of observed interferences as a function of time of day. The ordinate is the total number of minutes per associated hour interval during which interferences were observed in November

Fig. 2. Min/h interval during which interference was observed on GBR frequency. Solid block: November 1965. Hatched: December 1965. Cross-hatched: May/June 1962.

and December 1965. The cross-hatched blocks represent the 1962 observations made by Rohan and Allan.

It is interesting to note that there were few, if any, interferences during the average time interval in November 1965 for which NDT (at 35° N., 137° E.) reported that it was on its regular 17.44 Kc/s operation. On the other hand, NDT is not phase stabilized, which makes it doubtful that an interference of NDT with GBR could have been recorded with narrow-band phase tracking receivers. We believe therefore that the most probable location of the unknown interfering transmitter cannot be determined any closer after the fact, than by the boundaries given before.

We believe further that the GBR interferences observed by Rohan *et al.* and Allan in 1962 probably came from the same transmitter we observed in 1965, because of the similarity of the frequency offsets and times of interference.

We thank Mr. E. Naustvik of the Norwegian Institute of Cosmic Physics for the recordings; Mr. K. Yamada of the Radio Research Laboratories, Tokyo; Mr. S. Westerlund of the Geophysical Observatory, Kiruna; Professor R. Douglass, American University of Beirut; and Vice Comodoro L. Gallo, Escuela Superior de Aero-tecnica, Cordoba. We acknowledge the interference experiments conducted by Mr. R. Schaal, Mackenzie University, São Paulo.

## New Determination of the Magnetic Moment of the Proton in Terms of the Nuclear Magnetron

THE ratio of  $f_s$ , the spin precession frequency of the proton, to  $f_c$ , the cyclotron frequency, in the same magnetic field is equal to the ratio of the magnetic moment of the proton  $\mu_p$  to the nuclear magneton<sup>1</sup>  $\mu_n$ .

$$f_s/f_c = \mu_p/\mu_n$$

The ratio is used at present in combination with other experimentally measured constants to derive the best values for the atomic constants<sup>2</sup>. The uncertainties of current estimates of the Faraday constant, ratio of proton to electron mass, electronic charge, nuclidic mass unit and many other important constants are effectively determined by the uncertainty of  $\mu_p/\mu_n$ .

Our measurements were made at 0.47 tesla (4.7 k gauss). The spin precession frequency was measured with an amplitude bridge<sup>3</sup> and the cyclotron frequency using the omegatron method<sup>4</sup>. The omegatron was of the quadrupole type<sup>5</sup> and had split plates to improve the uniformity of the radio frequency field. Ratios of the masses of ions are known with great precision and may be regarded as auxiliary constants<sup>2</sup>. The cyclotron frequencies of hydrogen ions ( $H_2^+$ ), deuterated hydrogen ion ( $HD^+$ ) and deuterium ions ( $D_2^+$ ) were measured, and this enabled the shifts in the cyclotron frequencies caused by electrostatic fields to be eliminated.

The results of forty-three sets of three ion resonances, with standard deviations (including both systematic and random errors), are

$$\begin{aligned}\mu_p/\mu_n &= 2.792\,74 \pm 0.000\,05 \text{ without and} \\ \mu_p/\mu_n &= 2.792\,82 \pm 0.000\,05 \text{ (19 p.p.m.) with}\end{aligned}$$

the correction for the diamagnetism of the water sample<sup>6,7</sup>, respectively. This lies within 1.1 standard deviations of the present best value and midway between the values which were included<sup>4,8,9</sup> in the 1965 evaluation and those which were rejected<sup>10</sup> or too late<sup>11</sup> to include. It is hoped to increase the precision of the method by a factor of ten by working at higher magnetic fields.

This work forms part of the research programme of the National Physical Laboratory.

## Air Flow with Arc Present

THE behaviour of a flowing gas when disturbed by the presence of a high current arc has always been of great interest to circuit-breaker engineers and physicists.

The intense light of the arc under investigation is generally so much greater than that of the conventional background light source of the interferometer or Schlieren system used that it is extremely difficult, and in most cases quite impossible, to photograph the gas movement. This difficulty has been overcome by using a laser in place of the conventional light source of the interferometer system.

Fig. 1.

Fig. 2.

Fig. 1 is an interferogram of an arc between two horizontal electrodes; the intensity of the laser light source of the optical system is in this case comparable with that of the outer boundary of the arc.

The property of the laser to emit most of its light in a single intense spectral line allows a marked improvement to be made. Fig. 2 was taken with a laser light source, using a very narrow band interference filter between the arc and the camera which allows the light from the laser to reach the film, but cuts off practically all the light from the arc itself, except the relatively small continuum emitted at the laser wavelength. This interferogram shows no obliteration at all, and the fringes can be followed not only in the vicinity of the arc, but also right into the centre of the arc itself.

The records were obtained using a Schlieren polarization interferometer with one Wollaston prism and an analyser. The principle of operation of such an arrangement with a conventional light source has been given by Merzkirch<sup>1</sup>. It applies equally well to the laser light source, which has the additional advantage of simplified "setting up" procedure and very considerable improved quality of the fringes.

This work was a preliminary investigation to prove the principle of the idea, and the technique will now be applied to the study of gas-flow behaviour in the presence of high-power arcs.

## Operation of the Isobaric Spin Selection Rule in the $^{10}\text{B}(^4\text{He}, ^4\text{He}')^{10}\text{B}^*$ Reaction

THE second excited state of boron-10 at 1.74 MeV is thought to be the  $T=1$  analogue of the ground states of the neighbouring isobars beryllium-10 and carbon-10. If isobaric spin is conserved in the reaction  $^{10}\text{B}(^4\text{He}, ^4\text{He}')^{10}\text{B}^*$ , it should not be possible to populate a pure  $T=1$  excited state in boron-10 because both helium-4 and the boron-10 ground state have isobaric spin  $T=0$ . The conditions under which isobaric spin is expected to be conserved have been outlined previously by Lane and Thomas<sup>1</sup>.

Earlier experimenters<sup>2,3</sup> have searched for the 1.74 MeV state through the  $^{10}\text{B}(\text{d}, \text{d}')^{10}\text{B}^*$  reaction, but see no evidence for it. They have obtained an upper limit of 0.001 on the relative cross section for deuteron scattering to the  $T=1$  state compared with the average of the  $T=0$  states. For the reaction allowed by isobaric spin  $^{10}\text{B}(\text{p}, \text{p}')^{10}\text{B}^*$  the same experimenters observe scattering to both the  $T=1$  and  $T=0$  states. Similarly, in an earlier experiment, we have observed peaks corresponding to the lowest three excited states with the  $^{10}\text{B}(^3\text{He}, ^3\text{He}')^{10}\text{B}^*$  reaction, which, because  $T = \frac{1}{2}$  for helium-3, is the isobaric spin allowed for both  $T=1$  and  $T=0$  final states.

In the course of other experiments an opportunity arose to test the isobaric spin selection rule for the reaction  $^{10}\text{B}(^4\text{He}, ^4\text{He}')^{10}\text{B}^*$ . We have measured the relative cross sections for helium-4 scattering to the ground state and lowest three excited states of boron-10 at a laboratory angle of  $40^\circ$ . In the experiment reported here a 0.2  $\mu\text{amp}$  beam of helium-4 particles with an energy of 10 MeV, obtained from the Australian National University tandem accelerator, was incident on a target consisting of 20–30  $\mu\text{g}/\text{cm}^2$  of enriched boron-10 on a 5  $\mu\text{g}/\text{cm}^2$  carbon backing. The total beam passing through the target was measured by collection in a Faraday cup located at  $0^\circ$ .

The scattered  $^4\text{He}^{++}$  particles were momentum analysed with a 24-in. double-focusing spectrometer and detected with a solid state counter in the focal plane of the spectrometer. The energy spectrum from the detector was recorded in 200 channels of an 'RIDL' pulse-height analyser. A 0.0004 in. thick aluminium foil, placed in front of the detector, separated protons and  $^4\text{He}^{++}$  particles of the same magnetic rigidity and energy. A square aperture, with sides 0.5 in., placed immediately in front of the detector, defined the momentum interval accepted for counting. As this interval was less than the widths of the peaks, it was necessary to step across individual peaks with the spectrometer in order to obtain the total number of counts in them. The length of the steps corresponded, within experimental error, to the width of the defining aperture.

Fig. 1. The inelastically scattered particle spectrum of helium-4 corresponding to the three lowest excited states of boron-10. The values shown for  $Q$  near to each peak indicate the total charge collected in the Faraday cup for each data point in that peak.

The observed spectrum for inelastic helium-4 scattering to the lowest three excited states of boron-10 is shown in Fig. 1. The widths of the peaks are primarily caused by target thickness, kinematic broadening and detector resolution associated with the 0.5 in. defining aperture. The relative cross sections for scattering from the ground and lowest three excited states of boron-10 can be derived and are listed in Table 1. The estimated error in the relative cross sections is  $\pm 10$  per cent and is mainly caused by statistical errors and uncertainties associated with the lengths of the steps across the peaks as compared with the momentum interval accepted by the 0.5 in. defining aperture.

Table 1

Energy level (MeV)	$J^\pi, T$	Relative scattering cross section
0	$3^-, 0$	100
0.717	$1^-, 0$	12.6
1.74	$0^-, 1$	< 0.01
2.15	$1^-, 0$	6.8

The experiment provides no evidence for the existence of a group of inelastically scattered helium-4 particles which correspond to excitation of the 1.74 MeV  $T=1$  state and indicates that the isobaric selection rule is obeyed.

## Extension of the Sub-regular Solution Model for Binary Alloys

HARDY<sup>1</sup> applied his sub-regular solution model to the interpretation of activity/composition curves and to the calculation of solubilities in binary systems. The model provides an equation for the integral heat of mixing ( $\Delta H^M$ ) of the form

$$\Delta H^M = A_1 X_1^2 (1 - X_1) + A_2 X_1 (1 - X_1)^2 \quad (1)$$

which can be applied to systems which do not conform to the regular solution model where  $A_1 = A_2$ .

If  $X_1$  is taken as the atom fraction of component 1, then in equation 1,  $A_1$  can be shown to be  $\Delta H_{2,\infty}$  and  $A_2$  to be  $\Delta H_{1,\infty}$ , where  $\Delta H_{1,\infty}$  is the limiting value of the partial heat of mixing of component 1 as the concentration of 1 tends towards zero. Equation 1 can thus be rewritten in the form

$$\Delta H^M = \Delta H_{1,\infty} X_1 + (\Delta H_{2,\infty} - 2\Delta H_{1,\infty}) X_1^2 + (\Delta H_{1,\infty} - \Delta H_{2,\infty}) X_1^3 \quad (2)$$

By changing the ratio  $\Delta H_{1,\infty}/\Delta H_{2,\infty}$  from unity for the regular solution case to different values, integral heats of mixing curves of increasing asymmetry are derived.

Using the standard relation between the integral and partial quantities in a binary system<sup>2</sup>

$$\Delta H_1 = \Delta H^M + (1 - X_1) \frac{d\Delta H^M}{dX_1} \quad (3)$$

the equations for the partial heats of mixing can be derived from equation 2 and have the form

$$\Delta H_1 = \Delta H_{1,\infty} + 2(\Delta H_{2,\infty} - 2\Delta H_{1,\infty}) X_1 + (5\Delta H_{1,\infty} - 4\Delta H_{2,\infty}) X_1^2 - 2(\Delta H_{1,\infty} - \Delta H_{2,\infty}) X_1^3 \quad (4)$$

From equation 4 it can be seen that the composition dependence of a partial heat of mixing, even in the dilute solution range, depends not only on the value of the

partial heat of mixing at infinite dilution of the component under consideration ( $\Delta\bar{H}_1^\infty$ ) but also on the value of the partial heat of mixing of the other component at infinite dilution ( $\Delta\bar{H}_2^\infty$ ).

For a regular solution the partial heat of mixing always tends towards zero as the concentration of the component in the solution increases. For the sub-regular case, however, it can easily be shown using equation 4 that when  $\Delta\bar{H}_2^\infty = 2\Delta\bar{H}_1^\infty$  the composition dependence of  $\Delta\bar{H}_1$  is initially zero, and when  $\Delta\bar{H}_2^\infty > 2\Delta\bar{H}_1^\infty$ , initially the value of  $\Delta\bar{H}_1$  can move towards larger values as  $X_1$  increases.

This form of the sub-regular solution model provides a satisfactory description of the behaviour of the partial heat of mixing of gold in liquid tin which has previously<sup>3</sup> been found difficult to interpret. More recent work<sup>4</sup> has confirmed that the dependence on composition of the partial heat of mixing of gold in tin is zero at some temperatures in tin-rich solutions, but this work also showed that the value of  $\Delta\bar{H}_{\text{Sn}}^\infty$  was approximately twice that of  $\Delta\bar{H}_{\text{Au}}^\infty$  so that the sub-regular solution model would predict a very small composition dependence of  $\Delta\bar{H}_{\text{Au}}$ . The calorimetric results showed that at 450° C  $\Delta\bar{H}_{\text{Au}}^\infty = -7.85$  kcal/g atom and  $\Delta\bar{H}_{\text{Sn}}^\infty = -16.4$  kcal/g atom.

The asymmetry of the integral heat of mixing in the gold-platinum binary system<sup>5</sup> gives rise to partial heats of mixing, the composition dependence of which lead to the binary being considered in two parts<sup>6</sup>. This composition dependence has the form predicted by the present model using equations 2 and 4 if  $\Delta\bar{H}_{\text{Au}}^\infty/\Delta\bar{H}_{\text{Pt}}^\infty$  is substantially greater than 2. The values derived by Wagner are  $\Delta\bar{H}_{\text{Au}}^\infty = 5.8$  kcal/g atom  $\Delta\bar{H}_{\text{Pt}}^\infty = 1.9$  kcal/g atom.

From this it is clear that in order to understand the composition dependence of the partial heat of mixing of one component it is necessary to know the limiting values of the partial heats of mixing of both components of a binary system.

The regular solution theory<sup>7</sup> provides no explanation of why  $\Delta\bar{H}_1^\infty \neq \Delta\bar{H}_2^\infty$ . Kleppa<sup>8</sup>, however, has shown that increasing asymmetry of the integral heats of mixing curves is associated with differences in the valency of the two components. The values of the partial heats of mixing at present available are almost all derived from integral heat of mixing data. Before quantitative correlations can be shown between the ratios of the limiting values of the partial heats of mixing of the components and such factors as the valency and size differences, it will be necessary to obtain more accurate values of the partial heats of mixing by direct measurement. This has been done in the case of the gold-tin system<sup>4</sup> and other systems are being investigated.

### Interstellar Vehicle propelled by Terrestrial Laser Beam

IN a recent article Marx<sup>1</sup> examined the possibility that interstellar travel may be accomplished in the lifetime of an astronaut. He pointed out that the attainment of relativistic velocities by a rocket-propelled vehicle is hampered by the low efficiency, which is a result of the energy acquired by the ejected mass. Marx suggested

that if an interstellar vehicle were driven by the pressure exerted on it by a light beam transmitted from the Earth, then, because the recoil momentum and energy would now be acquired by an extremely massive body—the Earth—the energy wasted would be negligible.

Marx studies a model in which a plane wave of light of constant intensity  $I$  is reflected by a mirror of area  $f$  (the vehicle). The intensity of the reflected light is  $I'$ . Marx states that the momentum gained by the mirror in a time  $\delta t$  is

$$\delta p = f(I + I') \delta t/c = \frac{d}{dt} \left( \frac{M\beta c}{\sqrt{1-\beta^2}} \right) \delta t$$

and that the energy gained is

$$\delta E = f(I - I') \delta t = \frac{d}{dt} \left( \frac{Mc^2}{\sqrt{1-\beta^2}} \right) \delta t$$

The mirror is a perfect reflector, so the energy gained appears as kinetic energy (the rest mass  $M$  is unchanged). These equations are constructed with reference to a terrestrial frame, and are incorrect.

The correct equations for  $\delta E$  and  $\delta p$  can be found by equating the energy radiated by the transmitter in time  $\delta t$  to the gain in energy of the mirror plus the increase in the incident and reflected radiant energy, allowing for the fact that in the time  $\delta t$  the volume of space occupied by the radiation has increased on account of the motion of the mirror.

One then finds that

$$\delta E = f\{(1-\beta)I - (1+\beta)I'\}\delta t \quad (1)$$

and

$$c\delta p = f\{(1-\beta)I + (1+\beta)I'\}\delta t \quad (2)$$

From these equations and the relativistic expressions for  $E$  and  $P$  one can show that

$$I'(1+\beta)^2 = I(1-\beta)^2 \quad (3)$$

It is clear from (1), (2) and (3) that the rate of transfer of energy and momentum to the vehicle approaches zero as  $\beta$  approaches unity. The "instantaneous mechanical efficiency" defined as  $(dE/dt)/(If)$  does not rise to 100 per cent as claimed by Marx, but is found to be equal to  $2\beta(1-\beta)/(1+\beta)$ , which has a maximum value of 0.34 when  $\beta = 0.414$ .

The reason for the decrease in the efficiency is to be found in the fact that the intensity of the radiation measured in the rest frame of the vehicle decreases as the velocity increases.

The fact that the efficiency does not approach 100 per cent does not necessarily condemn this mode of propulsion. The question is whether or not interstellar distances could be covered in a time (in the rest frame) short compared with the lifetime of the astronaut, with a reasonable transmitter power. Thus one needs a relation between distance travelled ( $x$ ), time elapsed ( $t_0$ ) in the rest frame and transmitter power.

By putting  $\beta_0 = (dx/dt_0)/c$ ,  $\tau = (Mc^2)/(2fI)$ , eliminating  $I'$  from equations (1) and (2) and using the relativistic expressions for  $E$  and  $p$ , one can show that

$$\tau(dx_0/dt_0) = \sqrt{1+\beta_0^2} (\sqrt{1+\beta_0^2} - \beta_0)^2 \quad (4)$$

The solution to this equation is

$$x = c\sqrt{1+2t_0/\tau} (t_0 - \tau)/3 + c\tau/3 \quad (5)$$

If  $x$  is 100 light yr and  $t_0$  is 10 yr, then from (5) one finds  $\tau$  to be 0.022 yr. Choosing the superficial density ( $= M/f$ ) of the vehicle to be 0.01 gm<sup>-2</sup> (highly unlikely but extremely favourable), one finds that  $I$  is of the order of 1 MW cm<sup>-2</sup>.

Because we have been considering a plane wave, the area of the transmitter is the same as that of the mirror. Hence the radiate power is  $If$ . The lightest conceivable interstellar vehicle in which a man might exist for 10 yr would have a mass of 10 metric tons. Thus we find that  $f$  is of the order of  $10^9 \text{ cm}^2$  and the power radiated is of the order of  $10^9 \text{ MW}$ . This is so great that one does not need to consider the difficulties of arranging suitable deceleration and landing facilities.

## CHEMISTRY

### Effect of Bromine Derivatives of Malonic Acid on the Oscillating Reaction of Malonic Acid, Cerium Ions and Bromate

WHEN malonic acid, ceric sulphate and potassium bromate are dissolved in dilute sulphuric acid there occurs an oscillating chemical reaction which manifests itself by an oscillation of the light absorption which is caused by ceric ions (317  $m\mu$ ) and an oscillation of the rate of evolution of carbon dioxide. An oscillation of the potential of a platinum electrode dipped into the solution can also be measured<sup>1</sup>. Fig. 1 shows the light absorption at 317  $m\mu$  as a function of time in a solution of the above mentioned substances. The curve divides itself into four distinct sections: (a) disappearance of ceric ions; (b) reappearance of ceric ions; (c) stationary concentration of ceric ions; (d) oscillation. The cessation of the oscillation (not shown in Fig. 1) is usually abrupt, and the ceric ion concentration persists at the minimal value attained in the oscillation.

The disappearance of ceric ions in section (a) is caused by the oxidation of malonic acid by ceric ions. According to Sengupta and Aditya<sup>2</sup> this is a first order reaction, when there is an excess of malonic acid, and the oxidation products are carbon dioxide and formic acid. The stoichiometry of the reaction is supposed to be

The reappearance of ceric ions in section (b) is caused by the oxidation of cerous ions by bromate.

According to Zhabotinskii<sup>3</sup> this reaction is autocatalytic and requires an induction period before it starts. This was confirmed by the present author in experiments where no malonic acid was present.

Fig. 1. Light absorption of ceric ions (317  $m\mu$ ) as a function of time in a mixture of the following composition: 0.12 mmolar ceric sulphate, 0.60 mmolar potassium bromate, 48 mmolar malonic acid and 3 normal sulphuric acid at 60° C.

Fig. 2. Simultaneous measurement of evolution of carbon dioxide and potential difference of platinum and platinized platinum electrodes. Composition of reaction mixture: 0.83 mmolar ceric sulphate, 44 mmolar sodium bromate, 32 mmolar malonic acid and 3 normal sulphuric acid at 25° C.

The constancy of the ceric ion concentration in section (c) is supposedly the result of the competition between the ceric ion-consuming reaction (1) and the ceric ion-producing reaction (2). If this assumption is correct there should be a fast rate of evolution of carbon dioxide during this phase of the reaction. This was checked by an experiment in which the carbon dioxide evolution was measured in a Warburg apparatus. This apparatus does not allow a simultaneous spectrophotometric measurement on the reaction mixture, and so the reaction vessel was furnished with two small platinum wire electrodes one of which was platinized. By measuring the potential difference between these electrodes independent information about the progress of the reaction was obtained. Fig. 2 shows the result of simultaneous measurements of the carbon dioxide pressure and the potential difference between the platinum and platinized platinum electrodes as a function of time. It is observed that the different phases of the reaction which may be distinguished in the light absorption-time curve are easily identified in the curve showing the potential difference as a function of time. The rapid evolution of carbon dioxide during section (c) shows that reaction (1) proceeds rapidly during this phase of the reaction and, because the ceric ion concentration is nearly constant, reaction (2) must proceed with the same high rate.

The oscillation in section (d) is initiated by a fall in ceric ion concentration. This is supposedly caused by an inhibition of the autocatalytic reaction (2). The inhibitor is a substance which accumulates during section (c), and the inhibition is probably caused by the formation of a complex compound of the inhibitor and cerous ions, as suggested by Zhabotinskii. According to equation (2) bromine should be formed in this reaction, but no bromine is found. This is easily explained, because bromine and malonic acid are known to react very rapidly in acid solution to form bromomalonic acid and dibromomalonic acid<sup>3</sup>. Dibromomalonic acid decarboxylates to dibromoacetic acid which may be further brominated to tribromoacetic acid<sup>4</sup>. It was suspected that the inhibitor of reaction (2) was to be found among these four bromoacids.

The effect of adding an inhibitor of reaction (2) to the reaction mixture would be a shortening of the stationary phase of the reaction. The effect of adding the four

Fig. 3. Shortening of initial non-oscillatory phase of reaction caused by addition of bromomalonic acid, dibromomalonic acid, dibromoacetic acid and tribromoacetic acid to reaction mixture of the following composition: 9.78 mmolar ceric sulphate, 52 mmolar sodium bromate, 75 mmolar malonic acid and 3 normal sulphuric acid at 40° C. ■, Bromomalonic acid; □, dibromomalonic acid; ●, dibromoacetic acid; ○, tribromoacetic acid.

bromoacids already mentioned to the reaction mixture was examined by an experiment where the length of section (c) was measured at different concentrations of added bromoacid. The result is shown in Fig. 3 where the relative length of section (c) is plotted against the concentration of added bromoacid. It appears from Fig. 3 that all the four substances cause a shortening of section (c), but the inhibitory power of the substances does not increase in the chronological order of their formation, because dibromomalonic acid is a stronger inhibitor than dibromoacetic acid.

On the basis of this finding the oscillation may be explained in the following way. During the stationary phase of the reaction the bromine formed by reaction (2) attacks malonic acid to form bromomalonic and dibromomalonic acid. When a critical amount of dibromomalonic acid has accumulated, the gain factor (branching factor) of the autocatalytic reaction (2) turns negative and the reaction rate falls to practically zero. Reaction (1) is undisturbed and so the concentration of ceric ions falls. Simultaneously the concentration of dibromomalonic acid falls as a result of decarboxylation. The product of the decarboxylation, dibromoacetic acid, is a weaker inhibitor than dibromomalonic acid, and so the gain factor of the autocatalytic reaction again turns positive and, after an induction period, this reaction starts again. Now the concentration of dibromomalonic acid increases again and the cycle is repeated.

Fig. 3 shows that there is a remarkably sharp limit of concentration of tribromoacetic acid beyond which section (c) of the graph in Fig. 1 disappears. Furthermore, it was observed also that the oscillation disappeared when the concentration of tribromoacetic acid exceeded this limit. In the present experiment the critical concentration of tribromoacetic acid (0.81 mmolar) causing complete inhibition of reaction (2) is only a little larger than the total concentration of cerium (0.78 mmolar) and about one-hundredth of the initial concentration of malonic acid (75 mmolar). The aforementioned abrupt cessation of the oscillation at a low concentration of ceric ions is probably the result of a definitive inhibition of reaction (2) when this critical concentration of tribromoacetic acid has accumulated.

## Synthesis of Formaldehyde from Methane in Electrical Discharges

FORMALDEHYDE has been reported to be the chief product of the slow oxidation of methane initiated by electrical discharges<sup>1-4</sup>. The low energy yields so far obtained prevent this method from competing with the catalytic oxidation of methanol in the commercial production of formaldehyde.

We have investigated the effect of the presence of an aqueous phase on the synthesis of formaldehyde from methane-water vapour and methane-air mixtures. The formaldehyde is absorbed almost as soon as it is formed by a stream of water droplets falling in the discharge space. The partial pressure of formaldehyde in the gas phase and its decomposition by the electrical discharge are thereby minimized.

This technique has previously been described in the synthesis of hydrazine from ammonia<sup>5</sup>, and recent work has confirmed increased yields when, under similar conditions, the hydrazine is removed by a spray of ethylene glycol (Charlton, W., unpublished results).

The reactor used in the present investigations was a quartz tube, 20 mm in diameter, in which a high frequency (2.6 Mc/s) thermally cool discharge was established between an axial aluminium rod and an outer metallic conductor 5 mm wide. The water stream was atomized by passing it through a capillary tube entry nozzle together with the methane. A series of runs was conducted in which the rate of flow of water was varied from 2.7 to 56 g/min. All other variables were kept constant—the pressure was 80 mm mercury, the rate of flow of the gas was 360 c.c./min at N.T.P. and the power input in the reaction zone 30 W. The results are plotted in Fig. 1, curve 1, as the energy yield of formaldehyde in g/kWh against the rate of flow of liquid phase in g/min.

Fig. 1. Influence of liquid absorption in the synthesis of formaldehyde from methane and water vapour: (1) energy yield plotted against the rate of flow of the liquid; (2) percentage of formaldehyde absorbed; (3) percentage of water vapour in reacting mixture.

The temperature of the gas, approximately 30° C a few centimetres after the discharge zone, changed from run to run and decreased with increasing rate of flow of the liquid. Consequently, the percentage of water vapour in the reacting mixture also changed, as can be seen from curve 2 in Fig. 1, and was approximately constant for rates of flow of water in the range 30–56 g/min.

Curve 3 in Fig. 1 shows the percentage of the total amount of formaldehyde formed that is absorbed by the water droplets in or just after the discharge zone. This increases with the rate of flow of water until the concentration of formaldehyde in the gas phase approaches its

vapour pressure over water. Any further increase in the rate of flow of water has no noticeable effect on the rate of absorption beyond this point.

Curve 1 in Fig. 1 shows that the energy yield of formaldehyde increased from 0.68 to 1.5 g/kWh. The shape of this curve is dependent on the efficiency of absorption and the percentage of water vapour present in the gas phase—both of which are functions of the rate of flow of the liquid.

Further experiments were undertaken without the use of the liquid spray, and in these a mixture of methane and water vapour of the same composition as that obtained with a rate of flow of water of 30–56 mg/min was subjected to the discharge under similar conditions. Air cooling of the discharge zone was necessary in order to keep the temperature of the gas mixture at approximately 30°C. The energy yield of formaldehyde increased from 0.38 g/kWh without liquid absorbant to 1.5 g/kWh at a rate of flow of water of 30–56 g/min.

A parallel set of experiments was carried out with a gas mixture containing 37.5 per cent air. The energy yield of formaldehyde increased from 0.86 to 2.31 g/kWh at a rate of flow of the liquid of 20–60 g/min (Fig. 2, curve 4). With this system the amount of carbon

Fig. 2. Influence of liquid absorption in the synthesis of formaldehyde from methane and air: (4) energy yield plotted against the rate of flow of the liquid; (5) percentage of carbon monoxide in outlet gases.

monoxide formed was considerably greater than that previously noted. Curve 5 in Fig. 2 shows a sharp decrease in the percentage of carbon monoxide in the outlet gases as the decomposition of formaldehyde is quenched by its removal from the gas phase.

Although the yields of formaldehyde noted in the present work were still very low, these results show that a considerable improvement can be obtained by the use of liquid absorbents and that this technique may be decisive in systems where the energy efficiency is not far from being commercially attractive.

The two phase gas-liquid reactor has the distinctive advantage of reducing the residence time of the soluble products in the discharge without affecting the rate of input of energy/mole of reactant. In this way the yields of energy can be increased without reducing the conversion per pass. There is also the possibility that by a suitable choice of absorbent discharge induced reactions may be made more selective.

A further feature of the gas-liquid reactor is the ease with which the reactant and product temperatures can

be controlled over reasonably wide limits by virtue of the presence of liquid absorbent<sup>6</sup>.

### Simultaneous Determination of Several Charge-transfer Complex Association Constants using Nuclear Magnetic Resonance

A METHOD for determining the association constants of organic charge-transfer complexes in solution using nuclear magnetic resonance has recently been described<sup>1,2</sup>. For a series of solutions containing an electron donor species (*D*) and an electron acceptor species (*A*) which interact by a very fast reversible process to form a 1:1 charge-transfer complex (*DA*), if one of the reactants, say *D*, is in large excess over the second reactant, then<sup>3</sup>

$$\Delta/[D]_0 = -K_c\Delta + K_c\Delta_0 \quad (1)$$

where  $[D]_0$  is the total (free and complexed) concentration of the donor,  $\Delta$  is the observed chemical shift of a nucleus in *A* in the complexing medium relative to the shift of this nucleus in uncomplexed *A*, and  $\Delta_0$  is the shift of this nucleus in the acceptor moiety of the pure complex, again relative to the shift in uncomplexed *A*.  $K_c$  is the association constant defined by  $K_c = [DA]/[D][A]$ , where the concentrations represent the equilibrium values for the various species. A plot of  $\Delta/[D]_0$  against  $\Delta$  should yield a straight line, the gradient of which is equal to  $-K_c$  and the intercept with the ordinate equal to  $K_c\Delta_0$ .

Provided the condition  $[D]_0 \gg [A]_0$  (where  $[A]_0$  represents the total, free and complexed, concentration of *A*) the relationship between  $K_c$  and  $\Delta$  does not involve  $[A]_0$ . Consequently, if a series of solutions is made up, containing a common donor, *D*, and a series of acceptors  $A^1, A^2, \dots A^i \dots A^n$ , then providing the sum of the total (free and complexed) concentration of each acceptor,  $\Sigma[A]_0$ , is very much less than  $[D]_0$ , a series of relationships corresponding to equation (1) will hold for each equilibrium simultaneously.

It is therefore possible to determine the association constants of a set of complexes between a series of acceptors and a common donor (or vice versa) from measurements on solutions in which all the complexes coexist. Experimentally it requires that the various chemical shifts of the observed nucleus shall not overlap with one another in any given solution. In practice this is often not a severe restriction because the lines are narrow and they always move in the same direction when the concentration of the excess component is increased. Apart from the economy, the method also provides a means of comparing the complexing ability of a series of acceptors (or donors) in a common experimental environment.

The association constants ( $K_c$ ) for the complexes of hexamethylbenzene with the acceptors: ( $A^1$ ) 1,3,5-trinitrobenzene; ( $A^2$ ) 2,5-dichloro-*p*-benzoquinone; ( $A^3$ ) 1,4-dinitrobenzene; and ( $A^4$ ) *p*-benzoquinone in carbon tetrachloride have been determined simultaneously, and also in pairs. The values of  $K_c$  are compared with the values obtained when each complex occurs singly<sup>3</sup>. The results are summarized in Table 1.

Table 1. VALUES OF  $K_c$  (IN KG/MOLE) AND  $\Delta_c$  (IN C./SEC) FOR COMPLEXES OF HEXAMETHYLBENZENE WITH: ( $A^1$ ) 1,3,5-TRINITROBENZENE; ( $A^2$ ) *p*-BENZO-2,5-DICHLORO-*p*-BENZOQUINONE; ( $A^3$ ) 1,4-DINITROBENZENE; ( $A^4$ ) QUINONE IN CARBON TETRACHLORIDE AT 33.5° C

### Oxygen-Peroxide Couple on Platinum

On the basis of experience with carbon electrodes, the behaviour of platinum electrodes in the presence of oxygen-saturated electrolytes has been explained<sup>1-7</sup> in terms of the formation of peroxide. The experimental verification of the standard potential of the oxygen-peroxide couple on platinum in alkaline solution and its Nernst-dependence on the activities of the oxygen and peroxide has not, however, been published, although Bornemann<sup>8</sup> did study the couple in acid solution. As a part of this laboratory's investigation of fuel cell electrodes at simulated deep sea pressures, the oxygen-peroxide couple has been investigated on bright platinum<sup>9</sup>.

Fig. 1. Potential against the reversible hydrogen electrode (RHE) of smooth platinum electrode as a function of peroxide concentration. Dotted lines intersect at the concentration at which theory indicates change in potential control.

Measurements were carried out in stirred normal potassium hydroxide at 30° C on bright platinum electrodes previously subjected at least three times to a triangular potential sweep between 0.8 and 1.05 V. The effect of increasing peroxide concentration on the open circuit potential at 0.2 atmosphere of oxygen (Fig. 1) was a decrease in the potential of 30 mV for each decade increase in concentration below 10<sup>-4</sup> molar peroxide. Above 10<sup>-4</sup> molar peroxide, the potential shows only a small dependence on peroxide concentration of the order of -3.5 to -8 mV for each tenfold increase in concentration. Increasing oxygen pressure (Fig. 2) from 1 to 100 atmospheres increased the potential 30 mV per decade of oxygen pressure below 10<sup>-4</sup> molar peroxide and approximately 5-10 mV at concentrations of peroxide above 10<sup>-4</sup> molar.

The data for lower concentrations of peroxide obey the Nernst expression for the reversible reaction

as was observed by Berl<sup>1</sup> for carbon, and verifies the presence of the oxygen-peroxide couple on platinum. Geometrical extrapolation of the data and extrapolation of the results by means of the Nernst equation for the oxygen-peroxide couple to molar peroxide and 1 atm. of oxygen gives a standard potential of 0.762 V (against the reversible hydrogen electrode in the same system), compared with the thermodynamic value of 0.752 V. The small difference from the theoretical value can be attributed to depletion of the surface peroxide concentration from the bulk value because of its heterogeneous decomposition. This good agreement between experiment and theory is an additional confirmation of the controlling presence of the oxygen-peroxide couple.

Fig. 2. Potential of smooth platinum as a function of peroxide concentration and oxygen pressure. Solid lines indicate pure Nernst behaviour.

At concentrations of peroxide greater than 10<sup>-4</sup> molar a mixed potential is established which is determined by the catalytic decomposition of peroxide, as has been previously pointed out by Hoare<sup>7</sup>, the Gerischers<sup>4</sup>, Winkelmann<sup>5</sup> and Giner<sup>6</sup>. The appropriate reactions are

and

where  $k_1$  and  $k_2$  are the specific reaction rate constants for reactions 1A and 2. The observed open circuit potential is the potential at which the polarizing currents for the two half-cell reactions are equal. Solution of the kinetic equations corresponding to these reactions, assuming transfer coefficients of 0.5, yields a peroxide-independent potential, reported previously<sup>4-7,10</sup>. Using a value of 0.35 for a transfer coefficient of reaction (2), an increase of 5.0 mV for a tenfold increase in peroxide is obtained, in agreement with Fig. 1. The potential is also a function of the logarithm of the oxygen pressure in agreement with the data of Fig. 2, and a function of the logarithm of the ratio  $k_1/k_2$ . The specific rate constants can vary independently of each other, and depend, of course, on the state of the electrode.

We conclude that the rest potential of a platinum or any so-called inert electrode in an aqueous, oxygenated system can be described quantitatively in terms of both

the oxygen-peroxide couple and the mixed potential system based on reactions 1A and 2.

### Spectral Correlation of Transients with their Parent Derivatives in Aqueous Solution

THE spectra of many aromatic radicals have been summarized by Land<sup>1</sup> and Habersbergerova *et al.*<sup>2</sup>. The present experiments show a strict correlation between the spectra of some such radicals and their parent aromatic molecules. Cyclohexadienyl radicals derived from benzene and monosubstituted aromatic substances, with side groups directing electrophilic substitution into the *o* and *p* positions of the benzene ring, that is, with a negative  $\sigma$  Hammett function, were investigated by Dorfman *et al.*<sup>3</sup>. The effects of side groups with positive  $\sigma$  Hammett functions have been investigated only in benzoic acid<sup>4,5</sup>, nitrobenzene<sup>6</sup> and nitrosobenzene<sup>7</sup>. These observations have now been extended to the hydroxyl, hydrogen and electron adducts of benzaldehyde, acetophenone, benzonitrile and trimethylphenylammonium (TMPA) salt.

All the reagents used were of 'AnalaR' grade except for the triphenylammonium salt. Redistilled, deaerated water was used throughout the experiments. Pulse radiolysis<sup>8</sup> was used to generate hydroxyl radicals, hydrogen atoms

and hydrated electrons. Hydroxyl radicals were investigated in solutions saturated with nitrous oxide in which hydrated electrons are converted to hydroxyl radicals. Hydrogen atoms were investigated in solutions of pH 2. In the latter case hydroxyl radicals contributed to the transient spectra; the hydroxyl transient spectra were graphically subtracted. Hydrated electrons were investigated in either neutral or alkaline solutions in which hydroxyl radicals were scavenged by formate ions. The radiation doses were measured with a secondary emission chamber using a Fricke dosimeter for calibration. The monochromator was adjusted to give a band width of 10 nm.

Hydroxyl radicals react with aromatic compounds by addition giving hydroxycyclohexadienyl radicals<sup>9</sup>. The measured positions of the absorption maxima of the substituted hydroxycyclohexadienyl radicals are compared in Table 1 with those of the primary bands of the spectra of the corresponding parent molecules. In addition Table 1 gives the bathochromic shifts of these aromatic compounds caused by substitution, relative to the benzene primary band energy (*A*), and those of the substituted hydroxycyclohexadienyl radicals relative to the hydroxycyclohexadienyl radical band energy (*B*). Table 1 includes for comparison the results of other workers. The ratio *B/A* is approximately constant and has a mean value of 0.93.

The spectral characteristics of transients formed on reaction of hydrogen atoms with monosubstituted aromatic substances are very similar to the corresponding hydroxyl adducts and are given in Table 2 in an analogous way to Table 1. The ratio of *B/A* in this case has a mean value of 0.92.

In the spectra of both hydroxyl and hydrogen adducts the constant ratio relationship is less well obeyed by monosubstituted benzene derivatives with charged substituents.

Anions are formed when hydrated electrons react with the compounds listed in Table 3. The transient anions have spectra of a similar pattern to that of the parent molecules, with two well separated maxima but distinctly different from those seen in hydroxyl and hydrogen adducts. The transients from benzonitrile, benzoate and nitrobenzene gave a pH dependent protonation reaction. The anions derived from acetophenone and benzaldehyde

† Corcek, B., personal communication.

have been defined in isopropanol-water mixtures<sup>9</sup>. The ratio  $B/A$  is not constant in this case but decreases with increasing wavelength of the maximum of the primary band of the parent molecule, as shown in Table 3. All these molecules have substituents with positive  $\sigma$  Hammett functions.

It appears that reactions with hydroxyl (or hydrogen) radicals produce the same structure, namely, a substituted hydroxy (or hydro)-cyclohexadienyl radical from mono-substituted benzenes. Although the hydrogen and hydroxyl radicals have different electrophilic character ( $\rho_H = 0.71$  and  $\rho_{OH} = -0.41$ )<sup>10,11</sup>, the directing forces of as different substituents as  $-NO_2$  and  $-CH_3$  did not result in an obvious change in the transient spectra. The hydrogen and hydroxyl radicals may therefore be non-selective in their point of attack. The incoming hydrogen or hydroxyl radicals are located in the cyclohexadienyl radical outside the plane defined by the conjugated system. It is noteworthy that the influence of the substituents results in the same bathochromic shifts in the aromatic and the cyclohexadienyl systems.

It is expected that the relationships exhibited by the data in Tables 1 and 2 are generally applicable and therefore can predict the positions of the maximal absorptions of as yet unknown monosubstituted cyclohexadienyl hydroxyl and hydrogen adducts in water.

I thank my colleagues in the radiation chemical group of the Paterson Laboratories and in particular Drs. B. Cercek, M. Ebert, and A. J. Swallow for their interest and discussions during the progress of the work.

## BIOLOGY

### Fate of Unejaculated Spermatozoa

THE production of spermatozoa does not cease in sexually inactive males<sup>1-3</sup>, and it becomes necessary to examine the means of disposal of the surplus spermatozoa. The two most likely ways are either that they are voided in the urine or that they are resorbed in the epididymis or vas deferens. Early workers favoured the first of these

mechanisms because they found spermatozoa in the urine of rats, guinea-pigs, dogs, and men<sup>4,5</sup>. In 1931, however, Simeone and Young<sup>1</sup> reported that the vas deferens of the guinea-pig contained large numbers of degenerating spermatozoa and, as only small numbers of sperm were found in the urine, they concluded that resorption was the principal mechanism for disposing of the surplus spermatozoa.

Resorption has since been generally accepted as the principal means by which spermatozoa are removed from the epididymis, although doubts have been raised from time to time because histological investigations have usually failed to show extensive degeneration or phagocytosis of spermatozoa in the epididymis and vas deferens<sup>6-9</sup>. In rams and bulls with fistulated vasa deferentia, a constant flow of sperm through the fistula has been noted<sup>10-12</sup>, and observations on the elimination of radio-opaque material from the epididymis also suggest that the contents of the vas deferens pass into the urethra<sup>13,14</sup>.

The question cannot, however, be settled without quantitative estimates both of the number of spermatozoa produced and of the number resorbed or eliminated in the urine. Bielanski and Wierzbowski<sup>15</sup> reported as many as  $1.4 \times 10^9$  spermatozoa per day in the urine of rams, and this figure was probably of the same order as that of the daily production of spermatozoa by the testes<sup>16</sup>. We have therefore compared the daily sperm production (DSP) of rams, as estimated by an exhaustive ejaculation method<sup>17</sup>, with the output of spermatozoa in the urine by the same rams when sexually inactive.

Four Merino rams 5-7 years old that had been maintained in an animal house on a constant ration for 1 year were used. The rams had been subjected to exhaustive ejaculation tests at intervals of 6-10 weeks for the preceding 2 years. In each test eighteen ejaculates were collected on day 1, eighteen on day 2, and fifteen per day on days 3 and 4. The mean number of spermatozoa ejaculated per day on days 3 and 4 was taken as an estimate of the DSP. The number of spermatozoa per ejaculate drops sharply on days 1 and 2 but is fairly constant on days 3 and 4 (ref. 17). Table 1 gives the estimated DSP, together with the mean number of spermatozoa voided per day in the urine. Variation in the number of spermatozoa voided from day to day is large, and urine was therefore collected for 12-17 days. Collection was not begun for 15 days after the exhaustive ejaculation, as it was found that the output of spermatozoa in the urine was severely depressed for several days after the rams had been ejaculated a number of times. For rams A and B the estimate given in Table 1 is the mean of two ejaculation tests, one before and one after the period of urine collection.

In order to collect urine, a ram was put in a harness so that he could stand but not lie down, and a collecting apparatus<sup>18</sup> made of silicone rubber was strapped under the prepuce. The urine ran into a siliconed bottle containing 300 ml. of a 0.7 per cent solution of saponin containing 0.4 per cent formalin. The saponin prevented the sperm from agglutinating and the formalin inhibited bacterial growth. The bottles were changed daily and the total number of spermatozoa voided daily was estimated using a haemocytometer. Four separate samples were counted for each ram every day.

Table 1. DAILY SPERM PRODUCTION (DSP) ESTIMATED BY EXHAUSTIVE EJACULATION COMPARED WITH THE DAILY OUTPUT OF SPERM IN THE URINE OF THE SAME RAMS WHEN SEXUALLY INACTIVE

Ram	Mean daily output of sperm in the urine (in millions)	DSP estimated by exhaustive ejaculation (in millions)	No. of sperm in urine as percentage of estimated DSP
A	6,440 ± 1,210*	8,870 ± 750*	73
B	8,830 ± 1,650	5,710 ± 250	155
C	4,670 ± 450	7,060†	66
D	4,670 ± 540	6,410†	73

\* Standard error.

† Only two estimates available for these rams.

The results (Table 1) indicate that the mean number of spermatozoa voided daily in the urine of rams is of the same order as the estimated DSP (for all rams the mean daily number of sperm in the urine was 88 per cent of the mean estimated DSP). This further supports the suggestion that, at least in sheep, resorption in the epididymis, vas deferens or ampulla is not very important as a mechanism for disposing of the surplus spermatozoa in sexually inactive males. If this is so, then counting the number of spermatozoa in the urine of unejaculated males may be a simple method of estimating DSP in a variety of animals. Further investigations are in progress on the usefulness and accuracy of the urine method of estimating DSP. The estimates obtained by these investigations are being compared with those obtained by direct cannulation of the efferent tubules of the testis<sup>19</sup> in the same ram. Results are available to date for two rams. The mean number of sperm voided each day in the urine was 88 per cent and 102 per cent, respectively, of the DSP as estimated by testicular cannulation.

### Narciclasine: an Antimitotic Substance from *Narcissus* Bulbs

A SYSTEMIC research programme for the detection of eventual antigrowth factors in plant extracts revealed a potent antimitotic substance which was isolated from several varieties of *Narcissus* bulbs. The substance was called "narciclasine". Antitumour activity was observed by Fitzgerald *et al.*<sup>1</sup>, who used crude preparations of *Narcissus* bulbs. They found that pure alkaloids from the same source appeared to be inactive.

The substance was detected because of its very strong inhibiting activity on the growth of the radicles of wheat grains; crude extracts corresponding to 5 mg/ml. wet weight of the bulb gave an almost complete inhibition.

This test, which will be described in detail elsewhere<sup>2</sup>, allows good quantitative evaluations, and it was used throughout the procedure for the extraction and purification of the active principle. The bulbs, collected during the winter, were ground and extracted with 95 per cent ethanol. The ethanol was distilled out and the water residue repeatedly extracted with *n*-butanol. The butanol was taken to dryness at low temperature under reduced pressure, the residue extracted with hot acetone and the insoluble part discarded. The residue from acetone evaporation was chromatographed on a cellulose powder column, using acetone + 10 per cent water as eluent, and the active fraction was isolated by the same solvent using preparative circular paper chromatography, and utilizing its yellow fluorescence as a guide. From the paper it was extracted by methanol; its dry residue was dissolved in as little an amount of methylcellosolve as possible, and eight volumes of warm water added. A precipitate formed that was discarded by centrifugation. From the supernatant, kept overnight in the refrigerator, "narciclasine" precipitated as impure crystals. After repeated crystallizations from the same solvent mixture, from ethanol-water, or from glacial acetic acid, white crystals (melting point = 234°-235°), in the form of rosettes of long needles, were obtained. The yield varied from 30 to 100 mg/kg wet weight according to the variety of the bulbs used.

The substance was soluble in methanol, ethanol, *n*-butanol, acetone, ethylene, glycol, methylcellosolve and acetic acid; it was insoluble in water and in apolar solvents. It showed an intense yellow fluorescence in the ultra-violet region, gave a deep violet colour with ferric chloride and a blue colour with Folin Ciocalteu reagent. The reaction with diazotized sulphanilic acid and with diazo blue B was positive. It easily reduced ferricyanide in sodium carbonate solution. The Dragendorff reaction for alkaloids and the ninhydrin reaction were negative. The ultra-violet spectrum showed a sharp peak at 252 mμ with an  $E_{1\text{cm}}^{1\%}$  of 920. The structure of "narciclasine" has been almost fully elucidated<sup>3</sup>. This investigation suggests that it probably occupies a key position in the biogenesis of alkaloids of the Amarillidaceae. It inhibits the growth of the wheat grain radicles at very low dosages, and the inhibition is proportional to the log of concentration (Figs. 1 and 2). When tested on *Escherichia coli* Hpr (from the Microbiological Institute of the Milan University) in nutrient broth, a 50 per cent bacteriostatic inhibition of growth was induced by a concentration of 8 μg/ml. after 24 h.

"Narciclasine" was assayed for its action on cells of sarcoma 180 in ascites form, by intraperitoneal and subcutaneous injection and by oral administration at various dosages. A sharp antimitotic activity was also observed

Fig. 1. Wheat grains inhibited by narciclasine at concentrations increasing from 0.05 to 0.5 μg/ml. (lower row) in comparison with a control (upper row).

Fig. 2. Linear relationship between the per cent inhibition of growth of the lateral radicles and the log of concentration of narciclasine.

at very low doses and the subcutaneous route appeared the most effective. A colchicine-like effect was present at 0.5 mg/kg. A drastic decrease of the number of mitoses was seen 2 h after injection of 0.9 mg/kg, and after 4 h no more mitotic figures could be detected. As the dosage was increased the mitoses disappeared more rapidly and disrupted cells with globular clumps of chromatin appeared more frequently.

Mitoses reappeared sometimes at 18 h after the injection according to the dosage and the route of administration used. From an analysis of its antimitotic effect, "narciclasine" seems to act essentially as a metaphasic or a preprophasic poison and to have a mitoclastic activity especially at high doses. An  $LD_{50}$  of 5 mg/kg has been determined in mice by subcutaneous injection.

### Phagocytosis in Mammalian Hair

ON the basis of electron microscope investigations of the human hair follicle Birbeck and Mercer<sup>1</sup> suggested that pigment granules enter the cortical cells by phagocytosis. Swift<sup>2</sup> gave support to this suggestion by illustrating the close association between pigment granules and cortical cell membranes in human hair. During recent investigations on a range of less common animal hairs we have obtained much additional evidence in support of the view that phagocytosis is responsible for the ingestion of pigment granules into cortical cells.

Birbeck and Mercer<sup>1</sup> stated that they had never observed granules in the cuticular cells, although Swift (personal communication) has only rarely seen single granules in the cuticle of human hair. My work on guanaco and vicuña hair (two species of *Llama*), and swamp wallaby hair, has revealed the not infrequent presence of pigment granules within cuticular cells. To my knowledge this has not been previously reported.

Hairs were first reduced with a 0.5 molar solution of thioglycolic acid and then treated with a 0.05 molar solution of silver nitrate in accordance with the method of Dobb *et al.*<sup>3-5</sup>. Treated fibres were embedded in 'Araldite', sectioned on an ultratome, collected from deionized water on to uncoated 'New 200' grids, and examined in an electron microscope.

While single pigment granules have fairly frequently been observed in cuticular cells, the most interesting example is shown in Fig. 1, where a cluster of small gran-

Fig. 1. Thin section of the cuticle of swamp wallaby hair (silver treated,  $\times 24,000$ ).

ules is clearly evident in a cuticular cell of swamp wallaby hair. Guanaco hair also occasionally has clusters of this type, but so far the greatest incidence of these pigment inclusions has been found in the swamp wallaby hair, which also shows excessive pigmentation of the cortical cells, not only in large clusters, but also in strings, which often contain more than twenty granules.

In the cortex of swamp wallaby hair, in particular, there is ample evidence to support the view that a phagocytotic process is used to facilitate the entry of pigment granules into cortical cells, because there are numerous examples of the association between pigment granules and cortical cell membranes; and it is suggested that phagocytosis is also responsible for the inclusion of pigment granules in the cuticular cells.

The fact that pigment granules are rarely observed in cuticular cells of human hair, but are frequently found in the other hairs studied, suggests that differences exist between the various hairs in some of the stages of fibre growth in the region of the papilla. This point will require further investigation.

I thank Dr. J. Sikorski for his advice and encouragement in this work.

### Time required for Tumour Initiation by *Agrobacterium tumefaciens* on Pinto Bean Leaves

THE mechanism of tumorigenesis by *Agrobacterium tumefaciens*, the organism responsible for crown-gall tumours in plants, may be subject to critical experimental analysis in a host-pathogen complex only when the precise time during which tumour initiation occurs and the time required for the initiation of individual tumours are known. Knowledge of these time requirements and the factors influencing them may also provide insight into the number and kinds of processes involved in crown-gall tumour formation.

The initiation of crown-gall tumours in other host systems is remarkably sensitive to temperature<sup>1,2</sup>. The induction of normal tumours takes place at temperatures as high as 27° C but is completely suppressed at 32° C. By maintaining infected plants at 32° C and then at 25° C

for varying periods of time, Braun and Mandle<sup>3</sup> were able to show that tumour initiation occurred in *Kalanchoe* stems within 10–14 h at the lower temperature, if the plants were subject to the lower temperature at least 24 h after inoculation. The requirement of a 24 h preliminary period was interpreted as a host conditioning phase, as it proceeded in the absence of the bacterium<sup>4</sup>. In a previous paper<sup>5</sup> we have shown that treatments of infected pinto bean leaves at elevated temperatures are most effective in inhibiting tumour initiation if the treatment is begun 9–10 h after infection. Analysis of these results suggested this to be the time at which half the potential number of tumours was successfully initiated.

We have used temperature shifts between 27° and 32° C to determine the period during which tumour initiation takes place on the pinto bean leaf and to estimate the time required for individual tumour initiation.

Procedures for the pinto leaf crown-gall bioassay have been described<sup>6,7</sup>. The highly virulent strain B6 of *A. tumefaciens* was used to initiate the tumours. Eight infected plants (sixteen primary leaves) in an 8 in. pot were used to determine the effect of each temperature variation. The pots which contained the plants were placed in shallow pans of water in a forced air incubator at 32 ± 0.2° C or in an 8 × 10 ft. culture room at 27 ± 1° C immediately after inoculation. All treatments finished 72 h after inoculation and the plants were moved to a greenhouse. The tumours were counted eight days after inoculation. The infected plants were kept in the dark throughout the temperature treatment.

Raising the temperature from 27° to 32° C for 72 h immediately after inoculation (Table 1) allowed only a few per cent of normal tumour initiation to take place. The inhibiting effects of the higher temperature began after 16–18 h of treatment and with increasing time at 32° C a logarithmic decrease was observed in the number of tumours subsequently initiated. The six independent experiments in Table 1 were chosen to show that the amount of inhibition obtained by treatment at 32° C was independent of the number of tumours developing on the leaf, the variation in number of tumours in different experiments being caused by different concentrations of bacteria in the inocula and variations in leaf sensitivity.

In Table 2, three separate experiments are reported in which varying periods at 27° C replaced portions of the

72 h period at 32° C. Lowering the temperature by 5° for 2 h resulted in definite increases in the number of tumours initiated, regardless of the time at which the temperature was lowered. Extending the time at the lower temperature further increased the number of tumours. When the periods at 27° C were started immediately after inoculation, the number of tumours initiated increased logarithmically with time at this temperature. When the low temperature periods were begun 10 or 24 h after inoculation, however, the increase in tumour initiation with time at 27° C seemed to occur at two different rates, as though there were two distinct classes of tumours.

The control values designated as 100 per cent in each experiment in Table 2 represent the maximum number of tumours to be expected if, once the temperature has been lowered (to 27° C) (after 0, 10 or 24 h), it remains at this lower temperature for the rest of the 72 h period. A 10 h treatment at 32° C typically results in an increase in the number of tumours, while a 24 h treatment at this temperature results in about a 20 per cent reduction compared with the number of tumours observed when the entire 72 h period is at 27° C. If the temperature is lowered to 27° C after being kept at 32° C for 10 or 24 h, less time is required at the lower temperature for the same per cent tumours to develop, the longer the delay in subjecting the plants to the lower temperature (Table 3). The time at 27° C necessary to attain 10–100 per cent of maximum tumour initiation is reduced by 3–5 h when a prior treatment at 32° C is given. Thus, some of the events necessary for the initiation of tumours at many potential tumour sites (PTS) must occur at the higher temperature, allowing conversion of the remaining PTS to tumours in less time when the temperature is lowered. These events necessarily precede the process responsible for the lower temperature requirement.

Table 3. TIME AT 27° C REQUIRED TO ATTAIN VARIOUS PERCENTAGES OF MAXIMUM TUMOUR INITIATION, WITH AND WITHOUT PRIOR TREATMENT AT 32° C

Hours at 32° C before start of 27° C periods	Hours at 27° C required for tumour initiation*			
	10	30	50	100
0	7.5	13	16	19
10	4	10	12	14
24	4	9	12	—

\* Percentage of maximum number of tumours (see Table 2).

Two stages in temperature sensitivity were shown previously in this host<sup>5</sup>. The events which lead to the development of temperature sensitivity may be identical to those occurring at 32° C in these experiments, resulting in a shorter time requirement at 27° C to attain resistance to 32° C. Both kinds of experiments, therefore, are consistent in indicating a time requirement at many PTS before a temperature sensitive stage is observed.

From Table 2 it is obvious that tumour initiation by the crown-gall bacterium can occur on pinto bean leaves within 2 h at a conducive temperature. Thus, the minimum time required to convert a normal cell to a tumour cell must be less than 2 h and may be as short as a few min. Because the period during which tumours are initiated extends for at least 19 h following inoculation, preparation for tumour initiation must occur on the part of the bacterium, the host, or both at many PTS. Previous work has indicated that bacteria at many PTS require a period of metabolic activity, and possibly growth and cell division, before they can initiate tumours<sup>8,9</sup>. Braun<sup>2</sup> has shown that tumour, plant and inciting bacterium can grow well at 32° C, and concluded that this temperature inhibits tumour initiation by preventing the tumorigenic agent from reaching the host cell. We have reached similar conclusions in examining the inhibitory effects of short temperature treatments<sup>5</sup>. The bacterium may therefore be responsible for a portion of the lag in tumour initiation at many sites.

The pinto leaf host cells may also have to reach a critical state before tumorigenesis takes place, as has been demonstrated in the case of *Kalanchoe* stem tumours<sup>4</sup>. The generation of wound cambium in *Kalanchoe* proceeds

† Calculated from a mean per cent inhibition obtained from four comparable experiments.

faster at 32° C than at 25° C (ref. 10), showing that events leading to the cell divisions associated with wound healing may be promoted at 32° C. Because a critical stage in the wound healing process may be required for tumour initiation, these findings suggest that a host cell conditioning requirement may also be involved in determining the time required for pinto leaf tumour initiation.

A further alternative may be envisaged if the tumour inducing agent produced by the bacterium cannot accumulate. Under this restriction both the bacterium and the host cell would have to be in a competent state at the time of tumour initiation. Treatments inhibiting either might then determine whether tumour initiation occurs at individual sites, as well as the precise time of occurrence. The available evidence does not allow a decision as to the relative contribution of these alternatives to the 19 h requirement for the conversion of all PTS.

The time at 27° C during which pinto leaf tumours become able to withstand a temperature of 32° C is similar to the low temperature period necessary for tumour formation in stem systems<sup>3</sup>. The pinto leaf system, however, does not require the 24 h preliminary treatment which was shown to be a host conditioning phase<sup>4</sup> and the parameter measured is the number of tumours rather than the tumour size. Since the size of stem tumours seems to be directly related to the number of bacteria introduced into the wound<sup>11</sup>, as are the number of tumours per leaf in the pinto leaf assay, the close agreement between the low temperature time requirement in these two systems may be of significance.

The above results show that at 27° C the process of initiation of crown-gall tumours can proceed through the 32° C sensitive stage on the primary pinto bean leaf in a minimum time of under 2 h. Because all of the PTS are not able to withstand a temperature of 32° C until 19 h after inoculation, other events must take place at many sites before tumour initiation and these events determine the time at which the initiation process starts at these sites.

### Effects of a Soil Humic Compound on Root Initiation

HUMIC compounds are acidic dark coloured and predominantly aromatic substances that occur in soil organic matter in concentrations which range from close to zero to near 100 per cent. Because of their exchange capacity and ability to complex metal ions and hydrous oxides, these compounds affect the availability of nutrients to plant roots and biological systems, and also play an important part in the genesis of soils. Little is known about the more direct effects of humic compounds, such as those effects caused by uptake by plants and influence on plant metabolism. According to Russian workers<sup>1</sup> small concentrations of humic compounds, that is, up to 60 p.p.m.,

enhance root development and growth of a number of plants. Khristeva<sup>1</sup> believes that these compounds enter the plant during the early stages of growth and are supplementary sources of the polyphenols that serve as respiratory catalysts.

Heavy summer rainfalls may bring concentrations of humic compounds of the order of several thousand p.p.m. into the soil solution. The object of this investigation was to determine the possible influence of these higher concentrations on the initiation of roots.

The humic compound used originated from a podzol Bh horizon. Methods of extraction, purification and drying, as well as a number of physical and chemical characteristics of this organic matter, have been described previously<sup>2</sup>. The extracted and purified organic matter was soluble in both alkali and acid, so that, according to the definition accepted in soil science, it was fulvic acid.

Root initiation was measured as follows<sup>3</sup>: cotyledons were removed from 11-day-old bean seedlings (*Phaseolus vulgaris* L., C.V. 'Contender') which were grown on vermiculite; roots and etiolated stem tissues were rejected by trimming 2 in. below the cotyledonary node. The resulting leafy stem cuttings were placed in individual vials, each containing 0.25 ml. of 1/40 molar sodium bicarbonate solution either with or without fulvic acid. The cuttings completely absorbed the solutions within 3 to 3.5 h and were then trimmed through the cotyledonary node to leave 2-in. hypocotyl segments which were planted vertically (node-end exposed), 1.875 in. deep, in pots of 'Perlite' previously drenched with nutrient solution. Potted segments were overwrapped with polyethylene and held at 78° F to develop roots. The segments were removed from the 'Perlite' after six days and roots and initials counted under a magnifier-illuminator. Root counts reported here are averages of twenty-two segments.

Root formation was stimulated by fulvic acid concentrations greater than 500 p.p.m. (Fig. 1), reached a maximum at 3,000 p.p.m. and then remained more or less constant up to 6,000 p.p.m., which was the highest concentration tested. The pH of the 1/40 molar sodium bicarbonate solution was 8.4; pH values of bicarbonate solutions containing 1,500, 3,000 and 6,000 p.p.m. of fulvic acid were 7.1, 6.6 and 5.8, respectively. Treatments with pure 1/40 molar sodium bicarbonate solution (pH 8.4) produced the same root counts as treatments with distilled water (pH 5.5).

The presence of substantial numbers of COOH, phenolic and alcoholic hydroxyl groups in this fulvic acid<sup>4</sup> suggested that these groups might, at least in part, be responsible for the root initiation properties of the fulvic acid. Thus, each of the principal functional groups was blocked selectively by methods described elsewhere<sup>5</sup>. These preparations were dissolved in 1/40 molar sodium bicarbonate solution and administered at concentrations of 1,500 p.p.m. Blocking

Fig. 1. Effect of fulvic acid concentration on root initiation in beans. Average number of roots and initials on control segments:  $8.1 \pm 0.5$  (= 100 per cent). Controls received 1/40 molar sodium bicarbonate solution but no fulvic acid.

of practically all hydroxyl groups by acetylation reduced root initiation considerably, but blocking of COOH groups by esterification had no effect. Simultaneous blocking of both COOH and hydroxyl groups reduced root initiation to values of control samples which received 1/40 molar sodium bicarbonate solution only. This suggested that both types of functional groups in the fulvic acid were involved concurrently in reactions which resulted in increased root initiation.

A possible explanation for the experimental results lies in the known ability of the fulvic acid to form stable water-soluble complexes with di- and tri-valent metal ions<sup>4</sup>. Thus it is possible that the fulvic acid may aid in the movement of metal ions which can only be transported with difficulty within the plant. Iron is known to be essential to cell division and to the growth of roots<sup>5</sup>, but its mobility within the plant system appears to be severely restricted. In our tests the addition of 8 per cent ferric iron to 1,500 p.p.m. of fulvic acid resulted in a significant increase in root initiation over the application of 1,500 p.p.m. of fulvic acid alone.

These results suggest that humic compounds have significant effects on the rooting of plants in natural soils.

### Significance of Selenocystathionine in an Australian Selenium-accumulating Plant, *Neptunia amplexicaulis*

*Neptunia amplexicaulis* (Domin.) is a selenium-accumulating herbaceous legume endemic to Central Queensland. This species can accumulate selenium to more than 4,000 p.p.m. on a dry matter basis and is the main cause of clinical selenosis in livestock in some regions<sup>1</sup>. In previous work it was shown that <sup>75</sup>Se-selenite is metabolized by this species predominantly into ethanol-soluble compounds, with negligible labelling of the protein fraction<sup>2</sup>. This distribution contrasted strongly with the predominant conversion of <sup>75</sup>Se-selenite to seleno-amino-acids in peptide linkage in the proteins of several common pasture and cereal species<sup>2</sup>. The identity of the seleno-compounds present in *N. amplexicaulis* is therefore of considerable interest.

Three seedlings (with an average selenium content of 123 µg/seed) were grown for 6 weeks, to the stage of four compound leaves, in nutrient solution cultures which contained no added selenium<sup>3</sup>. The root systems were coiled in a small beaker and immersed in 4 ml. water containing 0.4 mc. sodium <sup>75</sup>Se-selenite (equivalent to 8 µg selenium). This solution was absorbed by the plants in 6 h and was followed by 0.001 molar calcium chloride solution over 24 h and finally nutrient solution<sup>3</sup> one-tenth of the strength over 64 h. The plants were continuously illuminated in a controlled environment cabinet over the period of absorption and metabolism of the selenium-75. They were then gathered, dissected into roots, stems and leaves, and frozen. Each tissue sample was ground under liquid nitrogen to a fine powder and extracted by stirring for 15 min with 50 ml. 80 per cent aqueous ethanol at room temperature. The extract was filtered, concentrated by rotary film evaporation at 35°

and 2 ml. was transferred to a small centrifuge tube. The pigment was removed from the leaf and stem samples with negligible loss of radioactivity by gentle extraction with 2 ml. ether. The aqueous solution was concentrated under a stream of nitrogen to a volume of 0.25 ml. and subjected to high voltage electrophoresis as a 30 cm band on acid-washed 'Whatman 3 MM' paper ('Miles Hivolt' apparatus, 6.0 kV, 300 m.amp. for 10 min in a pyridine/acetic acid buffer<sup>4</sup>, pH 5.3). Scanning revealed a small radioactive peak caused by the selenite ion and a larger peak (90–95 per cent of the total radioactivity in the extract) in the neutral amino-acid region, which was eluted with water. The solution was concentrated by freeze-drying, subjected to high voltage electrophoresis (6.0 kV, 300 m.amp. for 45 min in acetic/formic acid buffer, pH 2.0) and the dried electrophoretogram was autoradiographed overnight. The patterns of radioactivity were the same in root, stem and leaf tissues, with predominant labelling in two bands which were eluted. Each band (designated 1 and 2) was further purified by paper chromatography in *n*-butanol-acetic acid-water<sup>5</sup> and examined further.

The first band, which contained one-third of the radioactivity, was ninhydrin-positive and migrated identically with authentic selenocystathionine when the following separation procedures were used: paper chromatography in the solvent systems<sup>6</sup> *n*-butanol-ethanol-water, *n*-butanol-acetic acid-water and *n*-butanol-pyridine-water; high voltage electrophoresis at pH 9.2 (borate buffer<sup>4</sup>, 35 min, 'Whatman No. 1') and pH 2.0 (see above); and ion exchange chromatography at pH 4.7 on 'Whatman DE-20' paper<sup>5</sup>. Exact correspondence of ninhydrin-positive spots with autoradiograph images with or without added authentic selenocystathionine was observed in superposition tests. No evidence was obtained for the presence of compounds other than selenocystathionine in the first band.

Hydrogenolysis with Raney nickel<sup>6</sup>, followed by paper chromatography of the products in *n*-butanol-acetic acid-water, yielded only two ninhydrin-positive spots of comparable intensity, identified as alanine and  $\alpha$ -amino-butyric acid. Authentic selenocystathionine behaves similarly<sup>7,8</sup>.

Two-thirds of the radioactivity was contained in the second band, which was ninhydrin-positive and behaved as a neutral amino-acid on electrophoresis at pH 5.3 and 6.1. The unknown compound migrated faster than selenocystathionine on electrophoresis at pH 9.2, but slower at pH 2 and was clearly separate. Djenkolic acid and lanthionine both behaved similarly to the unknown compound on electrophoresis; the unknown compound, however, migrated between djenkolic acid and lanthionine on chromatography for 4 days in *n*-butanol-acetic acid-water<sup>4</sup>. On hydrogenolysis, the unknown compound yielded predominantly alanine; djenkolic acid and lanthionine yield only alanine. Related sulphur compounds have also been reported from seed of the legumes, *Albizia julibrissin*<sup>9</sup>, *Dichrostachys glomerata* and *Neptunia oleacea*<sup>10</sup>, which are all members of the Mimosaceae. Because analogous selenium compounds were not available for comparison the identity of this material remains in doubt.

The free amino-acids present in seeds of *N. amplexicaulis*, collected from seleniferous areas in Queensland, were also examined. It was shown by the above methods that selenocystathionine was a prominent amino-acid; additional colour tests with iodine-azide and nitroprusside reagents<sup>4</sup> were also consistent with this identification. The unidentified material of the second band was also present; both compounds are being isolated in milligram amounts for further characterization.

Selenocystathionine has previously been isolated from *Astragalus pectinatus*<sup>11</sup> (Papilionaceae) and *Lecythis ollaria*<sup>8</sup> (Myrtales) and identified in *Stanleya pinnata*<sup>12</sup> (Cruciferae). It is of interest that Se-methylselenocysteine is the principal seleno-amino-acid in several accumulator species (seven *Astragalus* spp.<sup>7,13</sup>, *Oenopsis condensata*<sup>7</sup>

(Compositae), *Stanleya pinnata*<sup>7</sup>). This compound could not, however, be detected in *N. amplexicaulis*.

The important characteristic which emerges from the distribution of selenium in *N. amplexicaulis* is its presence predominantly as two soluble non-protein amino-acids. Irrespective of whether <sup>76</sup>Se-selenite<sup>2</sup> or <sup>76</sup>Se-selenate was administered, 95 per cent of the <sup>76</sup>Se was soluble from the shoots and 75 per cent from the roots. The residual material was resistant to attack by proteolytic enzymes and after further tests was concluded to be elemental selenium<sup>2</sup>. The presence of selenium predominantly in the non-protein amino-acid fraction appears to be a characteristic of the accumulator species so far investigated. In non-accumulator plants, incorporation of selenium into protein amino-acids is the dominant feature<sup>2</sup>.

Accumulator species, therefore, may have evolved mechanisms for exclusion of selenomethionine and selenocysteine from proteins, which could be a factor in the tolerance of these species to high levels of selenium. No free or protein-bound selenocysteine or selenomethionine could be detected in *N. amplexicaulis*<sup>2</sup>. Exclusion of selenomethionine and selenocysteine from proteins might occur after their synthesis, for example, by specificity of amino-acid activating enzymes, or intracellular localization discrete from sites of protein synthesis. Alternatively these seleno-amino-acids may not be synthesized; in *N. amplexicaulis* the accumulation of selenocystathionine suggests an enzymatic discrimination against selenium analogues in the interconversion of cysteine and methionine. This hypothesis is supported by investigations of the selenium compounds present in the genus *Astragalus*. Whereas Se-methylselenomethionine is the principal soluble seleno-compound synthesized by four non-accumulator species, Se-methylselenocysteine is the soluble form synthesized by seven accumulator species<sup>14</sup>. Both selenomethionine and Se-methylselenomethionine were identified in pasture species<sup>2</sup>.

We thank Dr. P. B. Russell of Wyeth Laboratories, Philadelphia, for the gift of *Lecythis ollaria*.

### Light Requirements of Buried Seeds

It is well known that the upper layers of many types of soil contain large populations of buried, dormant seeds estimated to amount to many thousands per acre in some instances<sup>1</sup>. Many of these buried seeds are viable and germinate readily when the soil is cultivated or disturbed in other ways. There is good evidence that such seeds can remain dormant in the soil for long periods; indeed, evidence has recently been presented that seeds which have lain in the soil for as much as 1,700 years are still viable<sup>2</sup>.

The cause of this failure of buried seeds to germinate is not understood, although it has been suggested that high concentrations of carbon dioxide in the soil, lack of light or need for mechanical abrasion may be involved. It appears to be commonly held that "carbon dioxide narcosis", which was shown by Kidd<sup>3</sup> to occur in seeds of *Brassica alba*, is the factor most likely to control the dormancy of other species, but there is little direct evidence to support this view. On the other hand, the role of light in the germination of many species of seed is well known. Our present experiments suggest that a requirement for light may be the most important factor regulating the dormancy of many buried seeds.

The experiments were carried out at Aberystwyth on agricultural soil which had been continuously under pasture for at least 6 years, but which had been arable land in the past. After removing the top 2 cm of soil, samples were taken at various depths down to 10 cm. These operations were carried out in complete darkness. The soil was divided into 3 kg samples and sieved (3 mm mesh) under weak green light. Each sample was then divided into two equal portions. Each of these was then spread out in a thin layer in trays which were then maintained in a moist condition, either in light or in complete darkness in an unheated greenhouse. The subsequent emergence of seedlings was recorded at regular intervals.

Tables 1 and 2 summarize the results of such experiments over a period of 12 months. The emergence figures are the means of six replicates with the emergence in the dark expressed as a percentage of the total emergence in light. The most commonly emerging dicotyledonous species are shown in Table 2. We did not attempt to identify grass species.

Table 1 shows that there was a mean emergence in the dark of 4.4 per cent for grasses and 7.8 per cent for dicotyledonous species, giving a total emergence in the dark of only 6.1 per cent of the total emergence. The seeds which germinated in the dark may have been relatively fresh seeds which had been buried for only a short time, or old seeds which had been stimulated to germinate by the mechanical abrasion involved in sampling and sieving. The species shown in Table 2 as germinating in the dark trays were always represented in the light trays in much higher numbers.

From the results it would appear that a light requirement for germination is the chief factor controlling the

Table 1. MEAN NUMBER OF SEEDLINGS EMERGING AFTER 28 DAYS

Date	Condition	Grasses	Dicotyledonous species
November 1964	Light	14.0	7.0
	Dark	0.5 (3.6)*	0.5 (7.1)
August 1965	Light	19.0	7.0
	Dark	0.6 (3.2)	0.5 (7.1)
October 1965	Light	9.2	11.0
	Dark	0.6 (6.5)	1.0 (9.1)

All figures are means of six replicates.

\* Figures in parentheses express germination in the dark as a percentage of the total germination.

dormancy of buried seeds. This conclusion was fully confirmed by the results of the following field experiment.

Holes approximately 70 cm square were dug in a randomized experimental plot in the same field from which the samples in the earlier experiment had been taken. These holes were dug to depths of 5 cm, 15 cm and 30 cm in complete darkness except for weak green artificial illumination. They were covered either by sheets of glass or by sheets of asbestos, so that the surface of the soil was exposed to light or maintained in darkness, respectively. The number of seedlings which emerged was recorded, using a 0.25 square metre quadrat, placed centrally in the hole at 10, 21 and 35 days, again using only weak green illumination for the dark series. The average results of four replicates are shown in Fig. 1. These figures show the complete dependence of the germination of buried seeds on light, and also indicate a close relationship between the number of seedlings and depth.

Fig. 1. Number of seedlings per 0.25 square metre after 35 days. O, Light; ●, dark.

When the asbestos covers were removed from the holes after 35 days and replaced by sheets of glass, there was a rapid emergence of seedlings, but the emergence attained only about 50 per cent of the final value for continuously exposed plots.

Tests carried out on freshly harvested seeds of a range of species, to determine their light requirements, have shown that of the species listed in Table 2, numbers 1 to 7 inclusive are promoted by light, 8 to 16 are indifferent to light and 17 to 23 have not yet been tested.

The possibility that light is the principal factor controlling the germination of buried seeds after cultivation or other disturbances of the soil has probably been rejected because the seeds of many of the species involved have not been shown to require light when the fresh seed has been tested. The observation that some species of seed only required light when taken from soil samples suggests either that the burial of the seeds has in some way modified their reaction to light, or that in a given species there may always be a low percentage of seeds, usually so small as to be insignificant in germination tests, which require light, and that it is these seeds which remain dormant when buried. Borthwick *et al.*<sup>4</sup> have been able to induce light sensitivity in previously insensitive varieties of lettuce by heat treatment: and our own work has shown that by prolonged cold treatment it is possible to induce light sensitivity in seeds of locally collected *Stellaria*

*media*—the freshly harvested and after-ripened seeds of which appear to be indifferent to light.

## PHYSIOLOGY

### Enhanced Muscle Regeneration and Increased Strength in Myopathic Animals treated with Ethylenedinitramine

DIFFERENTIATION of skeletal muscle is activated as a function of replication<sup>1</sup>. This predicts that enhancement of growth in a myogenic system will increase the yield in new muscle. Excessive proliferation, however, can cancel muscle differentiation<sup>2</sup>. In employing the theory it is therefore necessary to stipulate that increased growth shall not reach deleterious levels (although just what these levels are cannot yet be specified). The properties of ethylenedinitramine (EDNA)<sup>3,4</sup> seemed, intuitively, to satisfy this condition. EDNA enhanced the regeneration of muscle under several specific conditions.

EDNA was converted to its ammonium salt and dissolved in physiological saline. Young, adult Swiss-Webster mice (for description see ref. 5) which had been wounded in their tibialis anterior muscles 45 h earlier received 0.1 mg of EDNA by intraperitoneal injection. Wounds were fixed 2 days later (96 h after wounding) and were examined histologically. Those from treated animals showed more regeneration than controls by a factor of almost four (Table 1). The effects of EDNA were much less pronounced when the compound was applied before or 24 h after wounding (Table 1). EDNA did not stimulate grossly premature unfolding of the signs of differentiation of new muscle. This was judged from the results of the following experiment: three mice with 45 h old wounds were given EDNA as before; the tissues, together with those of three untreated controls, were fixed at 84 h; that is, about 10 h before the advent of myotubes. (In regenerating mouse muscle, myotubes first appear in small numbers at 94.5 h after wounding. Within 1 h the density of myotubes increases almost tenfold and tends to hold steady until early in the sixth day when there is again another increase in number. These are unpublished observations of Pietsch and McCollister.) Serial examination of each section revealed not a single myotube among the controls or the EDNA treated specimens.

In another series the tibialis anteriors of male C57BL/6J mice with the same birthdate were punctured aseptically. Animals were divided into two equal groups. At 67 h those of one group received 0.1 mg of EDNA intraperitoneally. The others were untreated. All animals were given the equivalent of 10  $\mu$ c. of L-lysine labelled with carbon-14 (uniformly labelled with 200 mc./mmole) intraperitoneally

Table 1. EFFECTS OF EDNA ON REGENERATION IN MUSCLE AFTER SURGICAL INJURY

Experiment	Cases	Muscle fibres (regeneration/injured)	Index
Untreated	5	0.442 $\pm$ 0.076 S.D.	100.00
EDNA, 24 h before wounding	4	0.685 $\pm$ 0.077 S.D.	154.97
EDNA, 24 h after wounding	3	0.682 $\pm$ 0.045 S.D.	149.77
EDNA, 45 h after wounding	5	1.759 $\pm$ 0.220 S.D.	397.96

The above specimens were fixed and processed 96 h after wounding for reasons given in refs. 6-8. The rationale in the timing of experiments may be found in ref. 1. Three sections, about 10 per cent of the wound area, were randomly selected for counting in each case. S.D., Standard deviation.

Table 2. INFLUENCE OF EDNA ON SYNTHESIS OF ACTOMYOSIN IN REGENERATING MOUSE MUSCLE

	Specific activity*		Means
	Aliquot 1	Aliquot 2	
Controls			5,090
1	5,487	5,318	
2	4,660	4,762	
3	5,164	5,160	
EDNA-treated			7,997
1	6,325	6,206	
2	8,564	8,765	
3	8,818	9,009	

\* (D.p.m.  $^{14}\text{C}/\text{O.D.}_{275}$  actomyosin  $\times \text{O.D.}_{275}$  sarcoplasmic proteins) minus specific activity of actomyosin from uninjured tibialis anterioris.

117 h ( $\pm 3$  min) after wounding. Animals were killed 161 h after wounding, and their tibialis anterior muscles were dissected for the extraction of actomyosin. Synthesis of this protein complex was assessed by liquid scintillation counting. Specific activities, recorded in Table 2, were of the order of about 30 per cent to 80 per cent greater in EDNA treated animals than among controls.

The aforementioned evidence encouraged experiments with genetically dystrophic mice (*Re 129/dydy*). Muscle regeneration is spontaneous in these animals. Male *dydy* mice born within 3 days of each other were divided into two groups of three animals. One group was maintained on ground 'Purina' chow and the other on the food taken from the same bag and blended with 0.2 per cent (w/w) EDNA. The tibialis anterior muscles of these animals were prepared for histological examination 13 days later. There were appreciably greater numbers of myotubes in the muscles of the three EDNA treated animals than in their controls. To specify this in quantitative terms, eight sections (approximately 10 per cent of the muscle) were randomly selected from the tibialis anterior of a control and an experimental animal that happened to have been litter mates. The number of myotubes estimated for each unit area showed that the factor of increase in regeneration was approximately two (Table 3). During normal regeneration myotube nuclei increase progressively<sup>7,8</sup>. The numbers of nuclei in each myotube reflect maturation and therefore serve as an index of the quality of regenerative activity. Tubes with smaller numbers signal the advent of new foci of regeneration. Those with greater numbers indicate more advanced stages of differentiation. In control dystrophic specimens the number of nuclei in a myotube tended to cluster between four and ten, and in no control case were there more than twenty nuclei in a tube. In the EDNA treated cases the number of nuclei in each myotube varied considerably; there were many instances in which the number exceeded

Table 3. INFLUENCE OF EDNA ON REGENERATION IN GENETICALLY DYSTROPHIC MOUSE SKELETAL MUSCLE

Section	'Purina' chow (new fibres/mm <sup>2</sup> )	Section	'Purina' chow + EDNA (0.2 g/kg) (new fibres/mm <sup>2</sup> )	F
1	5.00	1	12.50	
2	5.17	2	15.18	
3	5.75	3	13.68	
4	11.32	4	15.18	
5	6.29	5	16.49	
6	5.77	6	16.96	
7	5.62	7	13.20	
8	7.89	8	11.38	
Means	6.60 $\pm$ 1.97 S.D.		14.32 $\pm$ 1.83 S.D.	57.749*

The bellies of left tibialis anterioris were trimmed into rectangular blocks and were sectioned tangential to the anterior surface. The data in the table were obtained for randomly selected sections of one control and one experimental case. These sections were examined with a dissecting microscope to ensure uniform density and while in place they were sized with a stage micrometer. The number of sections in which counts were made constituted approximately 10 per cent of the total. Tissues were alike with respect to density per unit area, size of non-regenerative muscle fibres and extent of degeneration.

\* Normal distribution of F (99 per cent) for 7 d.f. = 7.00.

Table 4. INFLUENCE OF EDNA ON REGENERATIVE ACTIVITY AS INDICATED BY THE NUMBERS OF NUCLEI IN A MYOTUBE

	Nuclei in myotubes (grouped)					
	2-3	4-5	6-10	11-15	16-20	21-37
Control	2	45	45	7	1	0
EDNA-treated	13	14	44	16	8	6

Using the specimens described in the legend to Table 2, ten sections were randomly selected; nuclei were counted in each myotube of each section. Eighty-two myotubes were found in the control sections and 149 in the experimentals. Values were equated to a hundred myotubes for simplicity.

twenty (see Table 4 for more rigorous examination of this point).

Dystrophic mice maintained on control or experimental regimens over a period of several months showed no differences in survival rates or body weight. Muscular dystrophy was in no sense "cured". After about 8 consecutive weeks, however, EDNA treated animals had gained feeble, although measurable use of their hind limbs (Table 5). Slow motion films of animals taken before treatment and after several months of feeding on EDNA revealed a pumping motion in the hind limbs that was not observable at the outset of the investigation nor in control animals.

Table 5. INFLUENCE OF EDNA ON CLIMBING ABILITY OF DYSTROPHIC MICE

Animal	Diet	No. of attempts	No. of climbs	Percentage climbs
Normal*	'Purina'	10	10	100
Normal*	'Purina' plus EDNA	10	10	100
Dystrophic†	'Purina'	8	2	25
Dystrophic†	'Purina' plus EDNA	10	9	90

There were four animals in the dystrophic, untreated group and five in each of the others. Each animal was tested twice. Learning became a variable in further testing. Treated animals continued to climb successfully. The untreated animals quickly learned, however, that falling bore no untoward consequences and eventually they made no attempts to sustain themselves. These factors contributed spuriously to the weight of the argument. The results recorded above represent the first two attempts made by the animals to accomplish the climbing task. The two successful climbs among untreated animals were achieved without the use of hind limbs. The treated animals were able to use their hind limbs and did so in all attempts.

† *Re 129/dydy*.

Effects of EDNA also were evaluated in pure bred beagle dogs. The dogs suffered a low-grade myopathy that had been induced by prolonged vitamin E deficiency and copper and selenium deprivation<sup>9-11</sup>. There were eight dogs, four from each of two litters born 4 days apart. Animals were brought into the laboratory as weanling pups. They were immediately started on the vitamin E deficient regimen with deionized water for drinking. A salt mixture free of copper and selenium was added to their diet along with vitamins other than E (refs. 9-11). One dog from each litter was kept on a normal kennel ration throughout the study. The deficient regimen was assayed with weanling rabbits (because of high sensitivity to vitamin E deficiency). Rabbits succumbed in 29 weeks. Estimating from the data of others<sup>12</sup>, our methods were roughly 40 per cent efficient in producing muscle lesions. Dogs were trained for 9 months. Each animal was taught to pull a sledge counterpoised with his body weight. The test course was 48 m, linear, smooth-surfaced, air conditioned and in a pressure-regulated room immediately adjacent to the kennel. Each animal ably and eagerly negotiated the 48 m, reproducing his performances within a fraction of a second. Weights could be varied  $\pm 10$  per cent without altering performance. Preliminary tests were conducted until there was no question that deficiently fed dogs went through the course more slowly than their normally fed siblings. In the test itself, each dog was clocked through the course at roughly the same time of day, twice weekly for 42 consecutive weeks. The test interval was subdivided into four experimental periods (I-IV). Each dog's performance was analysed individually on the basis of differences between periods. Comparisons between dogs were made on the basis of differential rather than absolute values. No EDNA was administered to any dog during period I. During period II three deficient dogs were maintained on a daily dose of 10 mg/kg of EDNA fed by capsule; the other three deficient animals were untreated. During period III EDNA was withheld. In period IV two deficient but previously untreated dogs were given the compound. Dogs, of course, were appropriately isolated at all times.

Data compiled in Table 6 and analysed in Table 7 leave little doubt that EDNA acted in some manner to enhance pulling capacity. About 4 consecutive weeks of treatment with the compound were required before beneficial effects were manifested. About a week after withdrawal of EDNA the previously treated dogs showed

Table 6. INFLUENCE OF EDNA ON PULLING CAPACITY OF DOGS

Dog	6-13 Weeks (I)	16-29 Weeks (II)	30-34 Weeks (III)	38-42 Weeks (IV)
Duke	19.7 ± 0.54	19.5 ± 0.52	20.0 ± 0.17	19.3 ± 0.85

## Action Potential Phenomena in Experimental Bimolecular Lipid Membranes

A MOLECULAR mechanism which develops multivibrator kinetics such as those shown in Figs. 1 and 2 has been constructed in experimental bimolecular lipid membranes by the methods given here. These electrokinetic phenomena are indistinguishable from cellular action potentials and include thresholds, refractoriness, delayed rectification, bistable flip-flop kinetics, anodal break excitation, self-regenerative changes of membrane potential accompanied by decreases in conductance, and spontaneous rhythmic firing, the frequency of which can be precisely controlled by varying the temperature and the applied electrical polarization. They are also reversibly blocked by local anaesthetics such as cocaine at physiological concentrations (2 per cent) and are modified in various ways by acridine and phenothiazine derivatives including chlorpromazine at concentrations of about 1  $\gamma$ /c.c.

The membranes, separating two aqueous phases, are made by methods presented elsewhere<sup>1,2</sup>. The membrane solution is composed of 2.5 per cent commercial purified sphingomyelin in  $\alpha$ -tocopherol:chloroform:methanol,

Fig. 1. Action potential and subthreshold response in an experimental bimolecular lipid membrane (upper) in response to applied rectangular constant currents (lower). Experimental conditions as in Fig. 3 except that potassium sulphate was used inside and 2 mg phosphatidyl serine were added to 1 c.c. of the membrane solution of the following composition: 0.06 g crude winter steer heart lipids, 0.05 g  $\alpha$ -tocopherol, 0.04 g tetradecane in 1 c.c. 3:2 chloroform:methyl alcohol. After the resting potential and delayed rectification were fully developed as in Fig. 3, protamine sulphate was added to give  $10^{-4}$  g/c.c. in the inside compartment. A few seconds of depolarization to +10 mV was required to initiate the protamine effect. After this action potentials appeared on stimulation as shown. Their threshold, amplitude and duration were constant provided the interval between stimuli exceeded the relative refractory period of about 10 sec. The resting membrane resistance was about  $10^8 \Omega \text{ cm}^2$ . Large decreases (10-30 times) and sometimes small increases in resistance accompany the action potentials, depending on the lipids. The geometry of the experimental system precludes the recording of propagated action potentials because the potential is macroscopically uniform over the entire membrane.

Fig. 2. Rhythmic action potentials. Experimental conditions as in Figs. 1 and 3 except that membrane lipid was purified sphingomyelin and potassium monohydrogen orthophosphate was used as electrolyte. Temperature  $40^\circ \text{C}$ . In sphingomyelin membranes spontaneous rhythmic firing in the absence of external polarization often occurs. It requires careful titration of EIM and protamine but is not yet under complete experimental control. With small depolarizing currents, however, rhythmic activity can always be induced and maintained for hours. Membrane lifetimes of 30 min-3 h are the limiting factor in this state. The rhythmic action potentials often show an initial spike and plateau like those found in heart muscle. The firing frequency increases with temperature. In this preparation the quasi-stable resting level was positive on the inside and the action potentials go towards the usual cationic resting potential level, that is, are inverted because of a slight excess of protamine. A small steady outward current maintains the rhythmic state. The resting membrane resistance was about  $5 \times 10^8 \Omega \text{ cm}^2$ . Except for the EIM these action potentials have also been made entirely from synthetic components (stearyl sphingomyelin and poly-arginine;  $\alpha$ -tocopherol). Synthetic aldosterone, 10 mg/c.c., generally strengthens the membranes.

5:3:2. The commercial product is usually repurified by silica gel *G* column chromatography as follows (Trams, E., personal communication). One gram of sphingomyelin is heated to boiling point in 20 ml. petroleum ether. Methanol is added until the solution is clear. This is then mixed with 10 g of 200 mesh silica gel and eluted from a column at 2 c.c./min with 60 c.c. each of petroleum ether; petroleum ether:chloroform, 1:1; chloroform:methyl alcohol, 1:1, 1:2, 1:3, 1:4 and 0:1. The last three fractions are collected under nitrogen, pumped dry and stored under nitrogen in glass ampoules below 0° C. Cadmium precipitates of crude acetone or methanol extracts of winter beef heart followed by removal of the cadmium<sup>3</sup> also provide useful membrane lipids.

After the formation of the membrane in 5 millimolar histidine chloride, pH 6.8, at 25° C, one compartment (denoted as the inside) is brought to a concentration of 10–50 mmoles/l. monohydrogen potassium orthophosphate or potassium sulphate and to 10<sup>-4</sup> g/c.c. of a crude proteinaceous excitability inducing material (EIM) obtained from *Aerobacter cloacae* A.T.C.C. 961 grown overnight in egg white media pH 6.8 at 37° C and stabilized by pan drying at 50° C or by lyophilization. As shown in Fig. 3, the membrane resistance then falls from 10<sup>8</sup> Ω cm<sup>2</sup> to 2 × 10<sup>6</sup> Ω cm<sup>2</sup> and a negative resting potential of about 50 mV develops on the inside in a few minutes. Under these conditions the system produces a strongly developed voltage restoring effect with applied depolarizing currents called delayed rectification. Protamine sulphate is next titrated into the inside compartment to an approximate concentration of 10<sup>-4</sup> g/c.c. After carefully adjusting the ratio of protamine to EIM, fully developed action potentials appear which include the single response to an applied pulse in Fig. 1 and the rhythmic firing shown in Fig. 2, as well as the other characteristics already mentioned.

The four components of the fully developed system are chemically specific. Histones, cholinesterase and other basic proteins cannot substitute for protamine. The protamine cannot act in the absence of EIM, which implies that it couples either directly or indirectly by way of the lipids with EIM in the membrane. This coupling requires sphingomyelin and is depressed by increasing the ratio of lecithin to sphingomyelin. EIM is itself sensitive to endopeptidase but not to exopeptidase (Trams, E., and Bukovsky, J., personal communication). It has a molecular weight of less than 10<sup>6</sup> and is dialysable through 'Schleicher and Schuell B20' membranes. It has also been found in acetone powders of human red cell ghosts and brewers yeast as well as in *Aerobacter* and *Serratia*. It has been purified two-thousand-fold after growing the bacteria in synthetic media and is then active at 10<sup>-8</sup>–10<sup>-9</sup> g/c.c. (Bukovsky, J., and Kushnir, L., personal communication). The final component, the salt gradient, also controls the nature of the electrokinetics. Monovalent anions tend to generate bistable flip-flop kinetics while phosphate or sulphate ions tend to generate monostable or unstable multivibrator kinetics, that is, single or rhythmic action potentials. Calcium (II) ions added in millimolar concentrations block rhythmic firing and change the thresholds. Except for secondary differences, EIM and protamine will function when placed together on either side of the membrane or in opposite compartments. Thus the direction of the ion gradient provides the only sense of polarity across the membrane.

It is thought that EIM develops channels which selectively conduct cations, develop potentials according to

Fig. 3. The development of conductance, resting potential and delayed rectification in a bimolecular membrane. The membrane, 1.0 mm<sup>2</sup> in area, was formed at 25° C, separating two aqueous compartments containing 5 mmolar histidine chloride buffer at pH 6.8. Test pulses were applied through series resistors which were usually kept higher than the membrane resistance so that the membrane current was constant during the pulse. The membrane potential was recorded with a differential cathode follower<sup>16</sup>. The first test of the membrane resistance was made by applying ±80 mV through a series resistance of 2 × 10<sup>8</sup> Ω which gave the two voltage pulses on the left. At the arrows, 0.1 c.c. of an 0.05 g/c.c. solution of crude EIM and 0.1 c.c. of a 2 moles/l. potassium chloride solution were added to one compartment of 4 c.c. and stirred. Shortly thereafter the membrane resistance began to fall and a resting potential appeared which was 50 mV negative on the side of the potassium chloride, defined as the inside. Within 2 min a strong delayed rectification appeared, that is, the membrane resistance and potential decrease during the applied constant outward currents. Under these conditions, the steady state current voltage, *I*(*V*), curve shows that the ratio of the membrane resistance (*R* = *V*/*I*) at the resting potential to that at zero potential can be as large as 1,000:1. After addition of EIM the conductance continues to rise linearly for periods from 30 min to several hours depending on lipid type and can reach 10<sup>-1</sup> mhos cm<sup>-2</sup>.

the Nernst equation and contain a dual gating mechanism corresponding to the two negative resistance region existing in the *I*(*V*) curve published elsewhere<sup>4</sup>. Protamine then apparently converts the selective conductance of a fraction of these channels to anions while leaving the gating mechanism unaltered. Thus two channel populations arise and the interplay between the voltage coupled permeability changes and the opposing electromotive forces of the two channel types generate the observed electrokinetic phenomena. This interpretation is consistent with the general requirements of the Hodgkin-Huxley theory for action potentials in squid nerve<sup>8</sup>, although in this case anion channels substitute for sodium channels, and a universal gating mechanism generates the permeability functions. Action potentials, produced by alternating cation-anion permeability, are found in algae, *Chara*<sup>9</sup> and *Nitella*<sup>7</sup>, and voltage controlled chloride permeability also contributes to action potentials in electroplax<sup>8</sup>. Although EIM does not show any appreciable selective conductance among the monovalent cations, this feature can be introduced into experimental bilayers by certain macrocyclic antibiotics such as valinomycin and nonactin, which develop as much as 160 mV between 0.10 molar solutions of sodium and potassium chloride<sup>9</sup>.

### Coupling a Sensory Artefact to the Brain

THE construction of artificial analogues of sensory receptors has recently become practicable. There are a number of electronic and electro-mechanical techniques for converting external stimuli into discharge trains similar to those initiated by receptors in the afferent peripheral nerves. It is more difficult, however, to devise satisfactory ways of coupling this type of mechanism to the brain so that the sensory influx provides information resulting in the evolution of a realistic motor programme. Although progress has been made in unravelling the "sensory coding" along some receptor channels<sup>1,2</sup>, much remains to be learned about the nature of sensory signals, their spatio-temporal organization and their interaction patterns. This communication briefly describes an attempt to couple a sensory artefact to brain, which uses a biologically destructive stimulus as an input source and which feeds a neural centre, the output of which has been empirically determined to be appropriate to such an input.

The radiation detector used in these experiments consisted of a small mercury two transistor power supply driven by batteries, which fed a Raytheon scintillation tube counter the output of which drove a Schmidt trigger feeding a small amplifier. Each radiation count resulted in the production of a square wave of 0.5 msec duration, adjustable in amplitude from 0.5 to 2 volts; this served as stimulus. The entire system was built up of miniaturized elements and mounted in an impact resistant plastic case slightly smaller than a cigarette packet which was fitted to a leather neck and chest harness worn without apparent discomfort by the cat. Stimuli were fed over a short length of insulated wire to a Winchester miniature octagonal plug mating with a female socket previously implanted in the skull. The implanted electrodes consisted of two stainless steel enamelled 30 gauge wires with tips sharpened to about 50 $\mu$  and separated from each other by 3 mm. A slightly coarser central shaft maintained the intertip distance and gave a firm purchase to the electrode holder of the stereotaxic instrument during implantation. Once the electrodes were in place and the dental cement had set, the central shaft was cut off close to the skull while the two leads were soldered into appropriate terminals on the under surface of the indwelling plug.

Four stimulation sites were used: ventro-postero-lateral (VB) and dorso-medial (DM) nuclei of thalamus, mesencephalic tegmentum (Teg), and sensori-motor cortex (Cx). Stimulation of the last site was achieved using a pair of stainless steel screws the blunted tips of which penetrated the dura. Parameters for position of the depth stimulation sites were selected through the use of the stereotaxic charts of Jasper and Ajmone-Marsan<sup>3</sup>. The position of the electrode tips was later checked histologically.

Of the five animals on which this report is based, each was provided with at least two sites for stimulation. Three cats presented dorso-medial and tegmental stimulation sites, while two carried ventro-postero-lateral and sensori-motor cortex stimulating electrodes. Four other animals were eliminated because of unsatisfactory histological control data and one because of apparent difficulties with the electrode insulation.

We used a radiation source of 1 mr. and a Heathkit Geiger-Müller radiation counter. The source was contained in a small cylindrical metal case about 2 cm in diameter and 1 cm in height and was already hidden when the animal was brought into the room. Different sites were chosen for each run to prevent the animal from associating a particular area with unpleasant sensations. The animal was allowed freedom to wander in a room (approximately 10 ft. by 14 ft. in size) which contained a number of familiar objects (feeding pan, box, crumpled paper) in or behind one of which the radioactive source was hidden. Animals were tested on alternate days, and every other run with the radiation sensor in place was a

"cold" run to prevent association of the pack with stimulation. Finally, each animal carried the pack on a total of only six occasions, three of them being tests with the source. The total stimulation period varied from 1 to 3 min, so that the chances of significant changes in the junction between tissue and electrodes were small. The histological controls were examined for evidence of damage at the electrode tips and changes were invariably minimal. Each run was watched by three observers, at least one of whom was ignorant of the site at which the radioactive source was hidden, and even with the character of the trial. Results were noted by each observer, then pooled and compared after all runs were finished and the animal had been killed.

Table 1 summarizes the electrode placements and the results attained in this investigation. In each of three dorso-medial implanted animals, entry into the radiation field resulted in immediate increase in motor activity, with crouching, tail lashing, and rapid head movement, accompanied by some variation of propulsive or retro-pulsive activity serving to move the animal out of the field. In every case except one, this field escape activity which removed the animal from the effective radius of the source (2-5 ft.) was completed in 3 to 10 sec. As soon as this was achieved, there was noticeable diminution of rapid motor activity, and a more leisurely sniff and search routine was reinstituted. On one occasion, cat R 5 froze at the border of the effective field (about 5 ft. from source) and remained in crouching stance, pilo-erected and tail lashing for at least 30 sec before slinking away.

Results of stimulation in the three other sites were variable, and in no case produced locomotor activity serving to remove the animal from the radiation field.

The introduction of sensory data from an artificial receptor directly into the central nervous system raises the problem of presenting such data in a meaningful manner. Because present knowledge of coding mechanisms is still inadequate to the task, other stratagems are necessary. The introduction of artificially induced signal trains into neural centres which produce empirically determinable outputs is one possibility, and has been of use in the self stimulation studies reported by Olds<sup>4,5</sup> and others.

In the present situation, an empirically demonstrated effect of dorso-medial stimulation is the output to which a stimulus from an appropriate input is matched. The studies of Roberts<sup>6</sup> among others have emphasized the effects of dorso-medial nucleus stimulation in cats, which include fear-like crouching and skulking with dilated pupils and—as stimulation voltages are raised—locomotor escape activity executed in a low slinking posture. In man, lesions performed stereotaxically in the dorso-medial nucleus produce apparent freedom from the suffering component in intractable pain<sup>7-9</sup> as well as much of the anguish in certain psychotic syndromes<sup>10</sup>. Anatomical analysis of this area suggests a very complex presynaptic

Table 1

Animal	Dorso-medial	Experimental results		Sensori-motor cortex
		Tegmental	Ventrobasal	
R2	Increased motor activity, tail lashing, backing out of field	Heightened sniff and search routines, looking around		
R3		No obvious effect		Raising right hind limb, licking foot
R5	Increased motor activity, pupillary dilatation, crouching, then forward slinking motion out of field			Turning head to right, preening right side
R7	Ears back, staring over one shoulder or other, slinking forward or sideways out of field		Scratching flank	
R10		Constant head turning, easily startled	Preening fur over right side	

field which combines elements of the ascending brain stem and thalamic reticular formations, the spinothalamic bundle, intrathalamic relays, tecto-tegmental systems, massive corticofugal bundles from prefrontal cortex and finer ascending components from hypothalamus<sup>11-15</sup>. Its position would appear to be critical for the integration of a number of specific, non-specific and autonomic components associated with nociceptive stimuli and vigilance. The output of the field appears associated in man and animals with very disagreeable effects often associated with motor patterns programmed to remove the organism from the stimulus if possible. In these experiments, all three of the dorso-medial implanted animals promptly instituted motor activity of one sort or another tending to remove them from an area apparently associated with discomfort or suffering. Because the source of these stimuli was a radiation detector and the intensity of intracerebral stimulation was proportional to the strength of the radiation field, it follows that the degree of motor escape activity instituted by our cats was some function of the intensity of the radiation field.

The possibility of directly mating artefacts to brain clearly remains limited until more is learned about the coding systems and about the techniques for artificially innervating neural fields. For most applications, it seems sufficient to convert stimuli for which no biological receptors exist into forms which can be interpreted. There may, however, be advantages in the introduction of certain physicochemical stimuli into the brains of animals unable to use artificial devices for converting such stimuli into usable data.

### Impulses from Single Nerve Fibres recorded in Man using Microelectrodes

Our knowledge of impulse patterns in the different types of afferent nerve fibres is based chiefly on animal experiments. It is true that Hensel and Boman<sup>1</sup> recorded action potentials from single cutaneous nerve fibres in man using the microdissection method, but this method cannot be used in routine clinical examinations. Moreover, it only allowed investigation of the cutaneous nerves and not of other types of nerve fibres. We therefore considered it of interest to develop a method for recording from single

nerve fibres in man using microelectrodes. For this purpose glass-coated platinum-iridium wire electrodes were used, made according to the method described by Wolbarsht and Wagner<sup>2</sup>. The wire had a diameter of 400 $\mu$ . It was electrolytically polished to a tip of 0.5–1 $\mu$ . As shown by Wolbarsht and Wagner, it is possible to free the metal tip from the glass insulation over a surface of optional size and thereby obtain electrodes of different impedance. In our electrodes the impedance ranged between 40 and 100 k $\Omega$  at 1,000 c/s. The electrodes were sterilized by immersion in boiling water for 20 min and then connected to a preamplifier with a cathode follower, the action potentials being displayed on an oscilloscope. A loud-speaker and a tape recorder with a frequency response of 400–19,000 c/s were also used.

The experiments were carried out on six healthy subjects between the ages of 20 and 30 years. All recordings were made from the ulnar nerve. After immobilizing the arm by embedding half the upper arm, the forearm and part of the hand in sandbags, the ulnar nerve just above the wrist was localized by determining the point on the skin at which maximal nerve action potentials were obtained when the little finger was stimulated electrically. The skin was cleaned both with 0.5 per cent bensenon spirit and with a 2 per cent chloramine solution and the micro-electrode was then inserted perpendicular to the skin surface into the nerve with the aid of a micromanipulator. Insertion of the microelectrode sometimes caused slight pain, but when it was held still with the tip in the nerve no pain was felt. A few of the subjects had mild paraesthesia in the hypothenar and/or little finger a few hours after the experiment, but none of them found this disagreeable, nor has any untoward reaction been encountered during the 6 months following the experiments.

Impulse activity was obtained from several hundred units and it was possible to record activity for several minutes—sometimes up to 20 min—from about seventy of these units in response to repeated skin stimulation or passive movements of the fingers.

Electrodes with high impedance were comparatively selective and recorded action potentials of 100–250  $\mu$ V amplitude which appeared to be unitary (Fig. 1A). They had an initial positive phase of very short duration, 0.2–0.5 msec, followed by a low negative phase of longer duration, which for the most part was due to the lower limiting frequency characteristics of the tape recorder. Conversely, electrodes with lower impedance generally picked up activity from more than one unit (B) and sometimes recorded composite action potentials varying in shape and amplitude from one discharge to another and

Fig. 1. Unit activity during tactile stimuli to the hypothenar (A) and fourth finger (C, D) and during passive abduction of the thumb (B). In every case the stimulus preceded the beginning of the sweep and outlasted the sweep. Records were obtained by playing back the tape recorder. In C and D the sweep was triggered by the first action potential, the foot of which is therefore not fully visible. Calibrations: in A, C and D, 200  $\mu$ V and 0.5 msec; in B, 200  $\mu$ V and 20 msec.

evidently originating from several units. Such action potentials are shown in *C* and *D*. They were evoked by gently stroking the dorsal surface of the first phalanx of the fourth finger. The shape of the discharges in *C* and *D* indicates that, on the whole, the same elements were activated in both instances.

The skin stimuli consisted of gentle stroking with the finger or a soft paint brush, or light pressure with the finger or a small blunt metal rod. Skin stimuli generally evoked brief discharges from several units but sometimes only a single discharge from one unit. It was possible to map out the receptor areas of the cutaneous fibres with a fair amount of exactitude. Movement of an interphalangeal joint elicited impulse activity which often continued during the greater part of the movement, but different units were active in different phases of the movement. A few units were activated by passive abduction of the thumb, which stretches the thumb adductor muscles. They responded with one or a few discharges during the movement. It is obviously not possible to state that the activity obtained emanated from muscle receptors as other deep and superficial receptors may also have been activated by the stimulus. It is, however, noteworthy that units activated by this as well as by other stimuli were all rapidly adapting. So far no units with tonic activity have been encountered.

The present investigation has established the possibility of recording impulses from single nerve fibres in man using microelectrodes without causing any appreciable discomfort or demonstrable injury. This technique presents new possibilities of studying the activity in different types of receptors in normal and pathological conditions.

## Intracellular Responses from the Grasshopper Eye

THE compound eye of the grasshopper (*Schistocerca gregaria*) consists of several thousand ommatidia which are arranged in an orderly manner along the radii of the eye. Each ommatidium contains from five to seven cells arranged so that their inner edges meet and form the rhabdome. A capillary microelectrode was introduced into a single ommatidium following a procedure described by Fuortes<sup>1</sup>. All experiments were performed on preparations mounted in a perfused oxygenated chamber. Light from an 8 W incandescent filament was attenuated as desired by neutral filters. At zero attenuation, the stimulus intensity was approximately  $3 \times 10^{15}$  photons (absorbable between 4 and  $6 \times 10^3 \text{ Å}$ )  $\text{cm}^{-2} \text{ sec}^{-1}$ . Penetration of ommatidial cells is presumably reflected by a negative potential of 40–70 mV which, in darkness, may remain constant for periods up to 2 h in exceptional cells. This potential decreases during illumination.

The response recorded intracellularly to a brief rectangular step of light consists of two readily identifiable parts—a transient and a late component (Fig. 1*A*). The transient component has been observed for 5.4 log units of stimulus attenuation. The transient increases in amplitude from a barely observable response and undergoes several modifications of configuration until, at the highest intensities of the stimulus, it reaches saturation very close to the resting membrane level. A plot of amplitude against the logarithm of the attenuation is sigmoid in

shape. The late component follows the transient and can persist, often at a rather constant amplitude, for several hundreds of milliseconds. The relation between the amplitude of the late component and the logarithm of the stimulus intensity is approximately linear.

The two components are increased after a long step of light (Fig. 1, right column). The responses in this sequence are quite similar to those observed in the dragon fly<sup>1</sup> except that the potential oscillation following the transient is more damped in *Schistocerca* and usually appears only at intermediate intensities of stimulation. In contrast with the response in *Limulus*<sup>2</sup> and the drone<sup>4</sup>, nerve impulses were not observed in this preparation.

A third component of the response to light which is not easily observable is a spike on the ascending limb of the transient. This is occasionally seen as a discrete entity but more often as a notch on the rising transient. It is barely noticeable on slow sweeps (Fig. 1*A*) but can be seen more clearly on faster sweeps (Fig. 1*B*). The spike becomes quite evident, in some cells, during hyperpolarization (Fig. 1*C*). In those cells which respond with an early spike, depolarizing current in darkness evokes this spike (Fig. 1*D*) but no other components of the response to light.

The passage of current through the microelectrode changes the potential across the cell membrane. Steady hyperpolarizing currents increase the change of potential evoked by light stimulation (Fig. 1*C*) but depolarizing currents decrease it. Fig. 2 is a plot of the transient

Fig. 1. Left column: *A*, superimposed responses to 25 msec steps of light of log attenuation 0, 0.6, 1.2, 2.1, 3.0, 3.9 and 4.8; impedance pulse is to far left. Interval between grid lines is 100 msec; *B*, response to zero attenuation stimulus of duration (lower trace) 22 msec for a different cell; *C*, response to zero attenuation stimulus at 1/sec before (left) and during (right) steady hyperpolarization of 2.5 nanoamperes for a different cell; stimulus duration, lower trace, is 22 msec; *D*, response to 1.5 sec depolarizing pulse of 3.5 nanoamperes in darkness; impedance pulse, on far left, precedes current pulse. Right column: responses to illumination with steps of light 7 sec long. The numbers in the top right-hand corner are the logarithm of relative light intensity. Discrete miniature potentials<sup>2</sup> are seen in the records at the greatest attenuations of stimulus which sum to give a "noisy" appearance to the response. Lower beam indicates duration of stimulus. For the entire sequence the time line is 1 sec and the calibration is 20 mV.

amplitudes evoked by three intensities of light during the passage of constant current.

Fig. 3 shows the relationship of the current and voltage of the cell of Fig. 1D. The relationship between current and voltage is linear for a short range before a hyperpolarizing response and rectification appear. Plots of the relationship of current and voltage from cells exposed to constant background light have different slopes from cells in darkness (Fig. 4). Membrane resistance is decreased in illuminated cells.

These observations have much in common with those made in *Limulus*, the dragon fly, the drone and the

Fig. 2. Relation between the amplitude of a light evoked transient and the intensity of a steady current through the cell membrane. The top, middle and lowest plots are the responses to stimuli of log attenuation 0, 1.2 and 2.1 respectively. Duration of the stimulus was 22 msec.

Fig. 3. Relation between the amplitude of the voltage change and the intensity of the current pulse through the cell membrane for the same cell as Fig. 1D. The response to depolarizing pulses (right) consists of a spike (closed circles) and a steady state component (bars). Slope of line through the linear portion of the curve, on either side of zero, is 7.7 Mohm.

Fig. 4. Current-voltage relation in a cell which did not exhibit an early spike. Circles and bars represent responses obtained in darkness and with zero attenuation background light respectively.

worker honeybee<sup>4</sup>. It seems reasonable to assume that after a light stimulus there is an increase of membrane conductance in the visual receptors which generates potentials with a transient and late component. In *Limulus*, the multiple spikes which are observed on this potential are probably generated at a distance from the recording site and represent axonal discharges<sup>3</sup>. In *Schistocerca*, however, light or currents produce only a single spike which increases in amplitude when stimulation is increased. I therefore suggest that this spike is a local response generated by the receptor and not a reflected response from the cell axon.

## MICROBIOLOGY

### Possible Extracellular and Intracellular Bactericidal Actions of Mouse Complement

THE pathogenicity of Gram-negative bacteria for mice has been related to their resistance to human or guinea-pig complement *in vitro* by Maaløe<sup>1</sup> and by Rowley<sup>2</sup>, while Jenkin<sup>3</sup> has suggested that serum factors are also involved in killing by macrophages. The use of human and guinea-pig complement in these experiments emphasizes the fact that no one has yet demonstrated bactericidal activity by mouse complement *in vitro*. Haemolytic activity, however, can be measured if special precautions are taken<sup>4</sup>.

Spiegelberg *et al.*<sup>5</sup> found that the clearance of dead *Escherichia coli* given intravenously to Swiss mice was reduced if complement had been removed by a previous injection of aggregated gamma globulin. By contrast, however, Stiffel *et al.*<sup>6</sup> failed to reduce the phagocytosis of *Salmonella typhimurium* when they de complemented Swiss mice by injection of egg albumin with anti-egg albumin. Moreover, clearance was the same in B10.D2 mice described by Rosenberg and Tachibana<sup>4</sup> as genetically lacking in complement.

This communication reports the results of some preliminary experiments using strains of *E. coli* sensitive to

complement (*WF* 96) and resistant to complement (*WF* 82) in *B10.D2* "old line" and *B10.D2* "new line" mice. These strains of mice are genetically identical except that the "old line" is genetically deficient in a component of complement probably corresponding to human  $C_6$  (refs. 7-9).

Bacteria were grown into the logarithmic phase in a minimal glucose medium<sup>10</sup> with added  $^{14}\text{C}$ -glucose. Under these conditions it is thought<sup>11</sup> that labelling is predominantly in the bacterial cell wall. Each strain of mouse was injected intravenously with each strain of *E. coli* in a dose of  $10^8$  living bacteria/100 g mouse. Blood clearance was followed by taking 0.05 ml. samples at intervals and measuring both the content of carbon-14 and the viable count.

At the end of 30 min the mice were bled and killed, and measurements of the carbon-14 content and viable counts were made on homogenates of liver, spleen and lungs. A calibration curve was made relating carbon-14 to viable counts in dilutions of the original inocula in which the viable count is known to equal the total count as measured by a Coulter counter. Total bacterial counts were then calculated for all samples of blood and organs on the assumption that there had been no loss of label and no bacterial multiplication. Control experiments using labelled *coli* in inactivated serum showed no loss of carbon-14 over a half-hour period but the viable count increased by about a quarter. If there is similar multiplication *in vivo* our calculated total counts are too low by about one-quarter because division reduces the activity of carbon-14 per bacterium.

Figs. 1 and 2 show the clearance curves for total and viable *E. coli* *WF* 96 (*C'* sensitive) and *WF* 82 (*C'* resistant) in *B10.D2* "old" and *B10.D2* "new" lines. Table 1 gives the corresponding phagocytic indices calculated from the early part of the clearance slopes as<sup>12</sup>

$$K = \frac{\log C_1 - \log C_2}{t_2 - t_1}$$

where  $C_1$  and  $C_2$  are the numbers of bacteria/ml. of blood at times  $t_1$  and  $t_2$  respectively. We have used the terms  $K_t$  and  $K_v$  according to whether  $K$  has been calculated from the total or viable counts.

For the *WF* 96 strains, which are sensitive to complement,  $K_t$  is the same in both strains of mice.  $K_v$  is

Fig. 1. Change of total and viable counts with time of *E. coli* *WF* 96 (*C'* sensitive) in the blood of *B10.D2* "old line" and "new line" mice. —●—, Total count "old line"; —▲—, total count "new line"; - - ○ - -, viable count "old line"; - - Δ - -, viable count "new line".

Fig. 2. Change of total and viable counts with time of *E. coli* *WF* 82 (*C'* resistant) in the blood of *B10.D2* "old line" and "new line" mice. —●—, Total count "old line"; —▲—, total count "new line"; - - ○ - -, viable count "old line"; - - Δ - -, viable count "new line".

roughly three times greater in mice with normal complement but only twice as great in the mice deficient in complement. In contrast, for the strains of *WF* 82, which are resistant to complement,  $K_t$  and  $K_v$  do not differ significantly and are the same in both strains of mice.

The finding that complement has little effect on  $K_t$  agrees with the results of Stiffel *et al.*<sup>6</sup>. The high  $K_v$  relative to  $K_t$  for *WF* 96 suggests killing of this organism in the circulation. The fact that in *B10.D2* "old line" mice this effect is less marked with *WF* 96 and absent with *WF* 82 suggests that it is due to complement.

The difference between the total and the viable counts of *WF* 96 in the blood increases markedly with time particularly in "new line" mice (Fig. 1). A much smaller difference develops with *WF* 82 (Fig. 2). Benacerraf, Sebestyen and Schlossman<sup>13</sup> found no difference in the clearance of live or dead *coli*, but they were measuring bacteria labelled with phosphorus-32 and not viable counts. If many bacteria are being killed in the circulation the question arises as to whether this is humoral or due to circulating phagocytes. Examination of stained blood smears showed 3,500-5,500 white cells/mm<sup>3</sup> with few bacteria in either cells or serum. Further investigation and differential counting are clearly required.

Table 2 gives the number of viable bacteria as a percentage of the total count in various organs. Underestimates of total count as already described explain why there are occasionally more viable than "total" bacteria.

The proportion of *WF* 96 surviving is greater in "old line" than in "new line" mice, by a factor of ten in the liver and of up to fifty in the lungs. The results are similar in the spleen except for an unexpectedly high proportion of survivors in one "new line" spleen. In contrast *WF* 82 shows much smaller differences between the two types of mouse and indeed in the liver survives rather less well in "old line" mice.

Table 1

Strain of mouse	<i>C'</i>	<i>WF</i> 96 ( <i>C'</i> sens.)		<i>WF</i> 82 ( <i>C'</i> resist.)	
		$K_t$	$K_v$	$K_t$	$K_v$
<i>B10.D2</i> "old line"	$C'_6$ defective	0.043	0.088	0.046	0.050
<i>B10.D2</i> "new line"	Normal	0.052	0.136	0.063	0.055

Phagocytic indices for *C'* sensitive *WF* 96 and *C'* resistant *WF* 82 strains of *Escherichia coli* in different strains of mice.  $K_t$  is calculated from total and  $K_v$  from viable bacterial counts.

Table 2. PER CENT OF BACTERIA FOUND VIABLE IN MOUSE ORGANS

Organ	Bacteria	Strain of mouse	
		B10.D2 "old line" (C <sub>3</sub> defective)	B10.D2 "new line" (normal C <sub>3</sub> )
Liver	WF 96	23	2
	(C <sub>3</sub> sens.)	23	2
		210	18
	WF 82	29	81
	(C <sub>3</sub> resist.)	45	100
Spleen	WF 96	74	169
		24	1
		35	13
	WF 82	38	111
		35	60
Lungs		81	64
		116	69
	WF 96	10	0.6
		25	0.8
	WF 82	51	0.9
		8	4
		15	7
		15	13

Thus within the organs the results again suggest that complement is important in killing bacteria, perhaps intracellularly. Unfortunately, because of the unexpected finding that considerable killing occurs in the circulation the results within the organs could also be explained on the basis that bacteria sensitive to complement are killed first and phagocytosed afterwards. Clearance experiments in whole animals are incapable of distinguishing between these two possibilities.

When evaluating the general significance of the results the possibility of species differences must be borne in mind. Roantree and Rantz<sup>14</sup> found that strains of *E. coli* isolated from patients with bacteraemia were likely to be resistant to complement. In rabbits, Roantree and Pappas<sup>15</sup> using a viable count method found that resistant strains of *coli* disappeared more slowly than sensitive strains at first and were more likely to reappear later. Rother and Rother<sup>16</sup> found that labelled killed *Salmonella typhi* were cleared from the blood at the same rate in normal rabbits and in a strain deficient in C<sub>3</sub>.

We agree with Rother *et al.*<sup>16</sup> and Stiffel *et al.*<sup>8</sup> that absence of a C<sub>3</sub> component has no effect on phagocytosis by the reticuloendothelial system. The absence of such a component, however, impairs the killing of an organism sensitive to complement.

Mouse complement may be inactive *in vitro*, but it is clearly bactericidal *in vivo*, probably extracellularly but perhaps intracellularly as well.

We thank Dr. G. Biozzi for his advice, the Smith Kline and French Foundation for a grant to cover the cost of mice and isotopes, Dr. N. Hughes-Jones and Dr. V. Wynn for allowing us time on their automatic scintillation counters, and Mrs. D. Gonzalez-Cadavid for excellent technical assistance.

## Wasting Syndrome in Thymectomized Immature Baboons (*Papio Species*) after Infection with Adenovirus Type 12

INDUCTION of neoplasms in newborn hamsters by the injection of adenovirus type 12 has been well established<sup>1-4</sup>. This virus has been found primarily in "normal" humans and then only infrequently<sup>5</sup>. The data presented here on the inoculation of immature baboons with adenovirus type 12 were obtained from a study designed to ascertain whether or not this virus would produce tumours. In order to enhance the oncogenic potential of the virus, thymectomy and splenectomy, irradiation and an immunosuppressive drug ('Imuran': 6-(1-methyl-4-nitro-5-imidazolyl) thiopurine) were used either singly or in combination.

The baboons (*Papio* sp.) were immature animals of ages varying from 3 months to approximately 3 yr with the majority under 1 yr of age. Experimental animals were maintained in strict isolation and were fed the standard ration used at this institution<sup>6,7</sup>.

The Hui strain of adenovirus type 12 originally obtained from Dr. J. J. Trentin (Baylor University School of Medicine) and adapted to baboon kidney cells (BKC), was used in this study. Repeated serum neutralization (SN) tests were performed (antiserum supplied by Dr. J. G. Winn, Communicable Disease Center, Atlanta, Georgia) to ensure specificity. Newborn hamsters were inoculated for oncogenicity. Passage of the virus back through HeLa or KB cells was done in order to maintain the titre. The titre remained virtually unchanged throughout the course of the experiment, that is, 10<sup>-3.5</sup>–10<sup>-4</sup> TCD<sub>50</sub>/0.1 ml. The stock virus remained free of pleuropneumonia-like organisms.

Each baboon received 50 ml. of undiluted virus suspension divided into intraperitoneal, subcutaneous, intrapulmonary and intravenous doses, with the exception of two animals (A-352 and A-373) which received 2.0 ml. by the same routes. Thymectomy and splenectomy were performed using standard surgical techniques<sup>8</sup>. Total body irradiation was from a cobalt-60 source which, when monitored, averaged 350–450 r. for each animal. 'Imuran' was given intraperitoneally in dosages analogous to those employed in human studies, that is, 3–4 mg/kg body weight daily.

Baboons were divided into groups receiving adenovirus type 12 either alone or in combination with: thymectomy and splenectomy; thymectomy, splenectomy and irradiation; 'Imuran'; thymectomy, splenectomy and 'Imuran'. In addition as controls two animals received only thymectomy and splenectomy; one animal thymectomy, splenectomy and irradiation; and two animals (D-101 and D-103) were maintained as uninoculated controls (Table 1).

Serological and virus isolation procedures employed in this study are considered standard for this laboratory and published elsewhere<sup>9</sup>.

Of thirteen immature baboons inoculated with adenovirus type 12 and which had either thymectomy, splenectomy, 'Imuran', irradiation or combinations of these procedures, six (46.2 per cent) have died at varying periods of time, 1–2 yr after inoculation (an additional animal (A.D-284) died by accidentally hanging itself in its cage). One thymectomy-splenectomy control and the only control animal with thymectomy and splenectomy plus irradiation died approximately 2 months and 1.5 yr following surgery and irradiation respectively. Although these two animals did not receive virus, they were kept in the same room with the infected animals and as a result were possibly exposed to infection. If all the thymectomized animals are considered, the mortality rate is 8 of 16 (50.0 per cent). Of the ten baboons considered as controls, five animals received only adenovirus type 12; three were thymectomized and splenectomized (one of these was also irradiated); and two animals were simply

kept in the same room with all these other animals. There has been one death (A-534) in the non-thymectomized-splenectomized group. These data, along with the experimental procedure used on each animal, are given in Table 1.

The mortality in the experimental series of animals is considerably in excess of the usual death rate in the Foundation's baboon colony, which has been 6-10 per cent over the past 3 yr.

During the course of the experiment a syndrome developed in this series of animals which resembled the "wasting" or "runt disease" reported in rodents<sup>10-13</sup>. X-ray evidence showed that seven of the animals had periosteal elevations particularly in the long bones (some more pronounced than others). These animals had a hunched posture with abnormal gait and general signs of debilitation. In addition to the above bone changes, nine of the animals evidenced weight loss. Two of the animals which received only virus showed marginal loss of weight and questionable bone changes on X-ray (Table 1). One of the three control animals died approximately 1-1.5 yr after inoculation. Alopecia occurred only in those animals which experienced weight loss and/or bone changes.

The animals which exhibited the most marked symptoms were A-594, A-539 and the two 'Imuran'-adenovirus type 12 animals, AD-283 and AD-289. Although the latter two did not develop bone changes, their weight and hair loss were extensive. The animal that killed itself

(AD-284) also exhibited early indications of this syndrome before it died.

Haematological studies performed regularly on each animal revealed only the development of transient leucopenia, eosinophilia and mild anaemia following irradiation<sup>14</sup>. Histological examinations have also failed to indicate conclusively or to suggest a cause of death. Bone lesions showed marked calcium depletion but no inflammatory or tumour cells. The compact bone layer was extremely thin as shown by fractures which occurred in two animals (A-539 and A-594). Histological examination of the parathyroids did not reveal anything.

All attempts to isolate an aetiological agent from any of the affected or dead animals have been unsuccessful. Bacteriological and mycological cultures have failed to reveal a pathogen. Attempts to recover adenovirus type 12 by passage of tissues in BKC, HeLa and WI-38 cells were negative. Four viral agents have been isolated from stool specimens. Neutralization tests indicated that these agents were not adenovirus type 12.

Development of antibodies as measured by complement-fixation (CF) and neutralization (SN) tests was extremely sporadic (Table 2). Animals which received a small virus inoculum (2.0 ml.) developed antibodies as expected, but erratic results were obtained in animals inoculated with 50 ml. of undiluted adenovirus type 12. Because of these results the animals were challenged with inactivated polio virus vaccine (Salk) obtained commercially. Again, the results were inconsistent and of little value for elucidat-

+ Antibodies present.

ing the immunological capability of these animals. A larger number of animals are evidently required in order to draw any definite conclusions.

Although "runt" or "wasting" disease has been reported in rodents following neonatal thymectomy and inoculation with various viral agents, this observation has been confined to newborn animals<sup>10-12</sup>, and has not been reported in a sub-human primate. A "runt" or "wasting" type syndrome was produced in immature (3 months to 3 yr) baboons which had been thymectomized-splenectomized and inoculated with adenovirus type 12 as well as in animals receiving the immunosuppressive drug 'Imuran'. Antibody production in these animals to both adenovirus type 12 and killed (Salk) polio vaccine was extremely erratic. Whether this reflects immunological incompetence associated with a reduction in the antibody production mechanism as described by Miller and others<sup>13,15-20</sup> or an overwhelming of the capability to produce antibodies by the large virus inoculum (50 ml.) used requires further investigation.

This investigation was supported by grants from the U.S. Public Health Service and the American Cancer Society.

### Adaptation and Growth Characteristics of Influenza Virus at 25° C

THERE have been many attempts to adapt influenza virus to growth at lower temperatures. For many viruses such as polio<sup>1-3</sup>, Japanese encephalitis<sup>4</sup> and measles<sup>5</sup>, a relationship has been observed between virulence and the ability to grow at lower temperatures, and this has been used in the selection of attenuated variants.

This study is an attempt to select a cold variant of influenza virus and to obtain practical data regarding multiplication of the virus in animal, tissue culture and embryonate eggs. A comparison of the ability of this

cold variant and the original strain to grow in different hosts and at different temperatures will be reported. The virus was propagated in primary chick kidney tissue cultures (CKTC) the management of which has been described elsewhere<sup>6</sup>, and in white Leghorn embryonate eggs between 10 and 11 days old.

Schematic presentation of the passage history of A<sub>2</sub>/AA/6/60 influenza virus  
Virus isolated in chick kidney tissue culture (CKTC) at 36° C

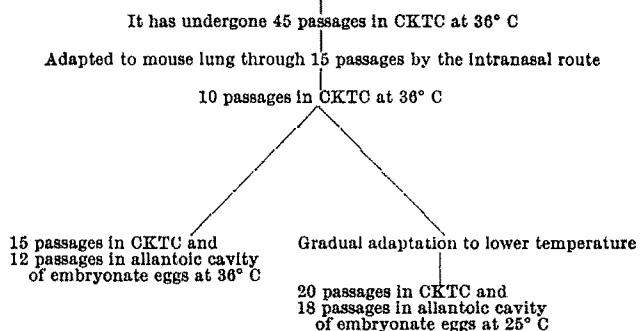

Fig. 1.

Fig. 1 is a schematic presentation of the passage history of the Asian strain (A<sub>2</sub>/AA/6/60) of influenza virus, which had been isolated from throat washings directly in chick kidney tissue culture at 36° C. After passage in tissue culture, the strain was adapted to mouse lung and then back again to tissue culture at 36° C. The process of growing the virus by gradually lowering the temperature of incubation was then undertaken.

Primary CKTC was infected by washing the monolayers free from serum and then allowing the virus inoculum to adsorb for 1 h at room temperature. Excess virus was removed and fresh maintenance media composed of double strength Eagle's basal medium<sup>7</sup> containing no serum was added. The incubator was 'BOD' equipped with a control system and a fan to ensure a uniformly low temperature with variation of  $\pm 0.1^\circ\text{C}$ . No selection or purification of the initial virus preparation was carried out before adaptation to growth at lower temperatures.

A sudden sharp decrease in the temperature of incubation was not successful. A gradual lowering of temperature was found essential for optimal growth (Table 1). The method followed was to grow the virus at an arbitrary temperature for 10 passages before lowering the temperature by 3° C. The data show that the infectious yield of virus from the initial passage at the particular temperature used was always about three logs lower than the corresponding tenth passage, where the infectious yield is maximal. No change in titre of the virus was noticed on further passages. Any further decrease in temperature of incubation did not seem to have additional advantages. This strain of virus was adapted to growth at 25° C,  $\pm 0.1^\circ\text{C}$ , initially in chick kidney tissue culture. It was then passed into embryonate eggs at 25° C so that no further adaptation was required. The pattern of growth of the virus in both host systems was approximately the same. Here the original strain refers to the virus exclusively passed at 36° C, while the cold variant refers to the virus passed at 25° C.

Table 1. INFECTIOUS TITRE OF INFLUENZA VIRUS (A<sub>2</sub>/AA/6/60) DURING GRADUAL ADAPTATION TO LOWER TEMPERATURES IN CHICK KIDNEY TISSUE CULTURE (CKTC)

Temperature used in °C	No. of passages at each temperature	Infectious titre (EID <sub>50</sub> /ml.) First passage	Tenth passage
36	60	7.5	7.7
33	10	5.7	7.5
30	10	5.0	7.3
27	10	4.3	7.3
25	10	4.0	7.0

Fig. 2. Growth curves of *A<sub>2</sub>/AA/6/60* strain of influenza virus and its cold variant in chick kidney cells. ○—○, Cold variant (25° C); × — × — ×, original strain (36° C).

Haemagglutination titre of the above growth curves

h after infection	Cold variant	Original strain
1	<2	<2
24	<2	<2
48	8	<2
60	32	2
72	128	16

A comparison of the growth of the original strain of the virus and its cold variant at 25° C is shown in Fig. 2. Primary chick kidney cultures were infected with high multiplicity of the virus at 25° C. Samples were taken at designated intervals and titrated at 36° C for infectious yield. It is apparent that the virus titre of the cold variant starts rising early and achieves a higher value than the titre of the original strain of influenza virus. The same pattern holds true when haemagglutination titre is determined, as shown in the legend to Fig. 2. The virus was found to propagate quite readily in both tissue culture and embryonate eggs at 25° C and the maximal value was reached between the second and the third day. Virus collection was always carried out at 72 h after infection. At 25° C the metabolic rate of tissue culture cells and growth of embryo is decreased. Moreover, cytopathic change, although evident, developed more slowly.

When growth patterns of the two strains were compared at 36° C the shape of the two curves was almost identical, but the maximal yield of the cold variant was lower at 36° C as compared with the original strain. There was no difference, however, in the appearance of cytopathic effects or in the extent of involvement of the cultures on infection with the two strains at 36° C.

The next approach was to compare the growth of both lines of virus at different temperatures. A pool of the two strains was made and titrated in embryonate eggs simultaneously at the three different temperatures, 25°, 36° and 40° C. Table 2 shows that the cold variant exhibits a markedly decreased ability to grow at 40° C—the titre is  $10^{-3.0}$  *EID<sub>50</sub>* as compared with the titre  $10^{-8.7}$  *EID<sub>50</sub>* of the original strain. The infectious titre of the cold variant is lower at 36° C, but higher at 25° C. The results also suggest that the original strain grows less efficiently at 25° C. The data presented permit the assumption that the main cause of differing values of the infectious titre at different incubation temperatures is the varying degree of thermoinactivation which exists and that 40° C can be used as a marker for characterization and differentiation of the two strains<sup>8,9</sup>. The relative stability of

Table 2. EFFECT OF DIFFERENT TEMPERATURES ON THE INFECTIOUS TITRE OF THE ORIGINAL STRAIN (*A<sub>2</sub>/AA/6/60*) AND ITS COLD VARIANT

Virus	Infectious titre ( <i>EID<sub>50</sub>/ml.</i> )		
	25° C	36° C	40° C
Original strain	4.5	9.0	8.7
Cold variant	6.3	7.5	3.0

this marker in the cold strain of the virus is at present under investigation.

Because we are also interested in determining if any degree of attenuation for mice is achieved by this process, as reported for other viruses, the original strain had been adapted to grow in mouse lung. Mice were then infected, using comparable egg infectious doses, by the intranasal route, with the original strain and its cold variant, and at selected intervals four mice in each group were killed and their lungs ground and titrated.

Fig. 3 shows the growth characteristics of the original strain and its cold variant in mouse lung. It is apparent that the cold variant shows moderate and delayed growth in the lung, the pattern resembling that of an unadapted virus; no lung lesions were evident in 72 h. The original strain, however, shows vigorous growth in the lung with no apparent delay in rise in the infectious titre, and maximum yield is reached 24 h after infection. Lung lesions were evident from the forty-eighth hour.

Table 3. RESPONSE OF MICE TO INFECTION WITH THE TWO STRAINS OF INFLUENZA VIRUS (*A<sub>2</sub>/AA/6/60*)

Dilution used to infect mice	Cold variant (25° C)		Original strain (36° C)	
	Mortality ratio	HI titre*	Mortality ratio	HI titre*
$10^{-1}$	4/10	1,024	10/10	—
$10^{-2}$	0/10	1,024	10/10	—
$10^{-3}$	0/10	512	9/10	1,024
$10^{-4}$	0/10	128	3/10	1,024
$10^{-5}$	0/10	<16	0/10	32

\* Haemagglutination-inhibition antibody at 21 days after infection.

Table 3 shows the comparative antibody response as well as the mortality ratio with different dilutions of the two lines. It is evident that there is a definite attenuation with a marked drop in the *LD<sub>50</sub>* mouse titre of the cold variant, regardless of whether the strain was passed in embryonate eggs or tissue culture. The virus seems to lose most of its ability to kill mice, but does infect, as evidenced by the good antibody response obtained. Infection with  $10^{-1}$  and  $10^{-2}$  dilutions of the original strain showed 100 per cent mortality, while infection with the  $10^{-3}$  and  $10^{-4}$  dilutions shows 90 per cent and 30 per cent deaths respectively. There was a good antibody response with the high dilutions used. This corresponds to infection of mice with the cold variant strain at  $10^{-2}$  and  $10^{-3}$  dilutions with no mortality and comparable antibody response. Even with infection at  $10^{-4}$  of the cold variant which is only 100 infectious doses, a good antibody titre was evident.

This line of research was considered encouraging in relation to qualities essential for an effective live virus vaccine<sup>10</sup>. Manipulations to attempt further characterization as well as adaptation of other recent strains of *A<sub>2</sub>* and type B influenza viruses are being carried out.

We have successfully adapted influenza virus to growth at 25° C in both tissue culture and embryonate eggs.

Fig. 3. Growth curves of *A<sub>2</sub>/AA/6/60* and its cold variant in mouse lung. ○—○, Cold variant (25° C); × — × — ×, original strain (36° C).

The cold variant appears to be heat labile and its growth at 40° C can be used as a marker of differentiation. A marked reduction in mortality of infected mice was observed. The cold variant appears to infect mice without overt pathological response, while stimulating good antibody responses. Thus a significant degree of attenuation has been achieved.

This investigation was conducted under the auspices of the Commission on Influenza, Armed Forces Epidemiological Board, and was supported by the Office of the Surgeon General, U.S. Army, Washington, D.C.

### Do Certain Colicines and Phages share Common Receptors?

THE receptors of bacterial cells for colicines have not so far been studied in great detail, but there is some evidence<sup>1,2</sup> for the assumption that the role of these receptors is to fix colicines specifically on to the bacterial surface and to enable them to have inhibitive effects like phage receptors<sup>3</sup>. Although it is generally accepted, this hypothesis has never been proved<sup>4</sup>. The main support for it came from Fredericq's later experiments, which showed a cross-resistance between certain colicines and phages. Consequently they are both supposed to be adsorbed on to common receptors. Thus colicine *K* should share a common receptor with the phage *T6* (ref. 5), colicine *M* with the phages *T1* and *T5* (ref. 6), etc.

All the receptors of *T*-phages are localized in the bacterial cell wall. Attempts have been made to define them in terms of the biochemical composition of the *Escherichia coli* *B* cell wall: the *T6* receptor is situated in the protein part of its lipoprotein layer<sup>7</sup>, while the *T5* receptor seems to be a lipopolysaccharide-lipoprotein complex<sup>8</sup>. The *T1* receptor has not yet been defined chemically.

From experiments with stable L-forms of *Proteus mirabilis* it is known that these cells which are devoid of their cell walls have lost their phage receptors and therefore are absolutely resistant to the action of phages<sup>9</sup>.

Recently a stable L-form of *E. coli* *B* has been isolated<sup>10</sup>. Preliminary experiments showed that this stable L-form, too, is resistant to the phages of the *T*-series. Thus it became possible to compare the action of both colicine *K* and phage *T6* on normal rods and on the cells of the L-form, that is, on cells with and without cell walls.

Plates of 1.5 per cent meat-peptone agar containing 15 per cent horse blood serum, 1.5 per cent or 3 per cent sucrose and 0.1 per cent magnesium sulphate (MgSO<sub>4</sub>·7H<sub>2</sub>O) were used in our tests. On to these, 6–8 days old broth culture of the stable L-form of *E. coli* *B* was densely seeded for every experiment and (a) broth suspension of the phage *T6* (10<sup>6</sup>, 10<sup>8</sup>, 10<sup>10</sup> particles/ml.), (b) broth solution of the colicine *K* (10<sup>10</sup>, 10<sup>11</sup> lethal units/ml.), and (c) broth (control) were dropped on to the dry surface. (For colicine *K* we used a filtrate of a broth culture of the strain *E. coli* *K* 235; the participation of the other colicine produced by this strain<sup>11</sup> was excluded by cultivating

the producer in meat-peptone broth under heavy aeration.) The experiment was repeated with various modifications.

In all cases the results were the same: the stable L-form of *E. coli* *B* is completely resistant towards the phage *T6* as well as towards all other phages of the *T*-series; however, at the same time, it remains fully sensitive towards colicine *K*. Together with its cell wall the L-form has evidently lost its receptors for *T*-phages, but not its colicine *K* sensibility, which means that the action of the colicine does not depend on previous adsorption on to a specific receptor in the cell wall.

Unfortunately, it is hardly possible to perform a similar experiment with the colicine *M* and phages *T1* and *T5*; it would be necessary to have a stable L-form of *E. coli* *B* resistant to colicine *V*, from which the colicine *M* cannot be separated. But the colicine *M* does not attack normal cells of *E. coli* *B*, which are specifically resistant to colicine *V*, in spite of the fact that the *B* strain is the classical indicator for *T*-phages. In this case, therefore, it is not possible to suppose a common receptor.

We conclude that the analogous sensibility of some strains towards certain colicines and phages cannot be simply explained by the assumption of common receptors. Reeves<sup>12</sup> has also stated that this assumption is open to serious criticism. The cross-resistance has never been found in 100 per cent of the strains covered.

The observation that specific cell wall receptors are not needed for colicine action at all—at least with certain colicines—will be thoroughly discussed elsewhere.

These experiments were performed at the Institute of Microbiology and Experimental Therapy, Jena.

We thank Dr. U. Taubeneck for encouragement and stimulating discussions, and Mrs. G. Elske for technical assistance.

### Bacteriocinogeny in Strains of *Providencia* and *Proteus morganii*

BACTERIOCINS<sup>1</sup> are a distinctive class of antibiotics produced by bacteria. Bacteriocins are proteinaceous and their action is limited to strains of the same or closely related species as the producer organisms.

Strains of a number of different families produce bacteriocins (bacteriocinogenic), but until the recent discovery of bacteriocin production in strains of *Proteus hauseri*<sup>2</sup> the *Proteus-Providencia* group were regarded as unique among the Enterobacteriaceae in being non-bacteriocinogenic<sup>1</sup>. This communication describes the presence of these antibiotics in strains of *Providencia* and *P. morganii*. The organisms used comprised the seventeen *P. morganii*, twenty-two *P. rettgeri*, twenty-four *Providencia*, twenty-eight *P. hauseri* and other strains of Enterobacteriaceae previously used<sup>3,4</sup>. A further seventy-

seven strains of *P. morganii* (labelled NM) and thirteen National Collection of Type Culture strains of *Providencia* were also investigated. The broth, solid media and phage techniques were those previously used<sup>5,6</sup>. The method for detection of bacteriocins was that of Craddock-Watson<sup>2</sup> with the use of 'Difco MacConkey' agar. Strains of *P. rettgeri*, *P. morganii* and *Providencia* were tested intraspecifically both for bacteriocinogeny and as bacteriocin indicators. Subsequently, all strains of the other species mentioned were tested for susceptibility to the bacteriocins. Many of these organisms are lysogenic<sup>3,4,7</sup> and phage activity was distinguished as follows: clear areas of inhibition on 'MacConkey' agar were cut out and suspended in 1 ml. broth containing a few drops of chloroform to sterilize the suspension. After the chloroform had been bubbled off, dilutions of the suspensions were spotted on a newly poured layer of the indicator organism. Lack of serial transmissibility of the inhibitory effect was taken to favour bacteriocin-like activity.

None of the *P. rettgeri* but streaks of five *Providencia* and twelve *P. morganii* strains produced areas of inhibition on indicator organisms (Fig. 1). No phage activity was demonstrated in the inhibition zones and the producer organisms were non-lysogenic by methods previously used<sup>3,4,7</sup>. The zones were confined in width to the original vertical streaks of producer organisms and there was little or no diffusion of the inhibitory agent even with prolonged periods of incubation before application of the indicator cross-streaks. Often the inhibition was confined to two narrow lines with normal growth of the indicator in between resembling the "D zones" encountered by Abbott and Shannon<sup>8</sup> (Fig. 2). Small doses of ultra-violet light applied to a 4 h growth of the vertical streak of the producer always changed the "D zone" of a system to a clear area of inhibition. Producer strains were active on a number of strains of the same species and the agent produced by *P. morganii* strain NCTC 2818 inhibited forty-three of the *P. morganii* strains. All seventeen agents could be distinguished by their spectrum of activity. None of the producer strains are inhibited by their own agents although some are sensitive to heterologous agents. The only extraspecies activity demonstrated was that of the inhibitory agent produced by *Providencia* strain NCTC 9190 on the *P. rettgeri* strain

Fig. 1. *Providencia* strain NCTC No. 9190 was streaked across 'MacConkey' agar and incubated at 37° C for 24 h. The growth was killed with chloroform vapour and scraped off with a sterile glass slide. Cross-streaks of *Providencia* strain NCTC 9263, *Proteus rettgeri* strain NCTC 7478 and *Providencia* strain NCTC 9211 were made and the plate incubated for 18 h. Strain NCTC 9211 is resistant to the bacteriocin produced by NCTC 9190. The other strains are sensitive.

Fig. 2. *Proteus morganii* strain NM 116 was streaked across 'MacConkey' agar and incubated at 37° C for 24 h. The growth was killed with chloroform vapour and scraped off with a sterile glass slide. Cross-streaks of *P. morganii* strains MR 21 and NM 104 and 121 were made and the plate incubated for 18 h. Strain MR 21 is resistant to the bacteriocin liberated by NM 116. The other strains show a "D zone" reaction of sensitivity described in the text.

NCTC 7478. Indeed, the latter strain is now used as indicator for this agent instead of the original *Providencia* indicator strain NCTC 9263. Table 1 lists the producer strains and one each of their indicators. No stably resistant mutants of an indicator strain have yet been isolated and in this respect the systems resemble *Pseudomonas aeruginosa*-pyocine interactions<sup>9</sup>.

Table 1. INCIDENCE OF BACTERIOCINOGENY IN *Proteus morganii* AND *Providencia* STRAINS

\* Only one indicator strain per bacteriocin is listed.

Overnight broth cultures of inhibitory strains sterilized with chloroform and centrifuged to clarity had inhibitory effects on indicator organisms. Titrations were done by spotting dilutions on 'MacConkey' agar. When the spots had dried the plates were covered for 5 min with filter paper disks which had been soaked in a suspension of the indicator strain. Results were read after about 16 h at 37° C. Inhibitory titres up to 1/20 were obtained. Titres ten-fold higher could be obtained by applying small doses of ultra-violet light to logarithmically growing broth cultures in shallow layers, and then incubating in the dark for 6 h before addition of chloroform. All the agents are bactericidal as determined by subculturing from clear areas of inhibition to fresh agar. Solutions of the bactericidal agents diffuse 1 cm or more overnight from a central sealed hole in 'MacConkey' agar as determined by application of the indicator filter disk the next morning. The reason why little or no diffusion is detected by the

cross-streak method may be because the agents adsorb to producer organisms. The agents are retained by dialysis tubing and this method was used to obtain a fifty-fold increase in titre. Inhibitory titres could not be increased by centrifugation at 24,000g for 2 h, and differential centrifugation procedures used to concentrate *Proteus* phages for electron microscopy resulted in total loss of activity. The agent liberated by *P. morganii* strain NCTC 2818 is inactivated at 70° C for 30 min but not at 65° C. The other agents are inactivated at 65° C. The agents are susceptible to the proteolytic enzymes of *P. vulgaris* strain OX19 as determined by a modification of the method of Fredericq<sup>10</sup>. The agents of *P. morganii* strains NCTC 2818 and NM 38 are least susceptible, while those produced by *Providencia* strains are totally inactivated. The detection of the agents is dependent on the medium used. In this respect they resemble the variability of colicine production in different fluid media<sup>11</sup>. No activity could be demonstrated on nutrient agar or in 'Difco' nutrient broth and this may explain previous failures to demonstrate this type of activity in the species concerned.

The bactericidal agents described conform to the definition of bacteriocins and the only member of the *Proteus* group which has not yet proved bacteriocinogenic is thus *P. rettgeri*.

### Effect of Calcium Ions and Pentachlorophenol on the Respiration of *Micrococcus lysodeikticus*

THERE has been much work on the effect of divalent cations and of uncouplers of oxidative phosphorylation on mitochondrial respiration, but little is known about the effect of these substances on bacterial respiration at whole-cell level.

We have examined the effect of calcium ions on the endogenous respiration of *Micrococcus lysodeikticus*, and the effect of pentachlorophenol, an effective uncoupler of the oxidative phosphorylation of membrane fragments of *M. lysodeikticus*<sup>1</sup>, has also been examined.

The conditions of culture of *M. lysodeikticus* will be described elsewhere (unpublished results of Fujita and Ishikawa). The cells were washed well with 5 mmolar *tris* hydrochloric acid, pH 7.4, containing 1 mmolar EDTA before use. A Clark type oxygen electrode was used; it was equipped with a plastic cell with an internal volume of about 3 ml. The experiments were carried out at 22° C–23° C.

In Fig. 1 the effect of added calcium ions on the cellular respiration in *tris* buffer is shown. The stimulation of the respiration by calcium ions occurs at a rate much slower than in a similar experiment with mitochondria<sup>2</sup>. Thereafter the rate of respiration progressively decreased until it became less than the initial rate. This decreased respiration after stimulation, on addition of calcium ions, was temporarily designated as "calcium ion-inhibited respiration". The addition of 0.1 mmolar pentachlorophenol affected the calcium ion-inhibited respiration only slightly if at all, but a later addition of 1.4 mmolar inorganic phosphate reactivated the calcium ion-inhibited

respiration. If pentachlorophenol was added to the cells suspended in *tris* hydrochloric acid buffer containing no calcium ions, the oxygen consumption (calcium ion-free respiration) was inhibited immediately and the inhibition was removed by addition of phosphate (Fig. 2).

When the reaction proceeded in phosphate buffer the addition of calcium ions induced a progressive decrease in the rate of respiration as in *tris* buffer and the addition of pentachlorophenol released the oxygen consumption (calcium ion-inhibited respiration) instantaneously (Fig. 3).

We therefore recognized that pentachlorophenol plus inorganic phosphate released the calcium ion-inhibited respiration, whereas pentachlorophenol alone inhibited the calcium ion-free respiration. The latter inhibition was relieved by a subsequent addition of phosphate.

If it is possible to assume that the calcium ion-inhibition of respiration mentioned here reflects the accumulation of inactive intermediate as a result of coupling between electron transfer and cation incorporation<sup>3</sup>, it can be concluded that pentachlorophenol plus inorganic phosphate dissociate the non-phosphorylated intermediate which is involved in the incorporation of calcium ions. Fragments of the sonicated protoplasmic membrane of *M. lysodeikticus* have been observed to undergo a progressive inhibition of the oxidation of NADH in the presence of calcium ions (unpublished results of Fujita and Ishikawa). There is, however, no satisfactory interpretation of the inhibition of respiration by pentachlorophenol in the absence of inorganic phosphate.

Fig. 1. Effect of calcium ions and pentachlorophenol on the endogenous respiration of *M. lysodeikticus*. *Tris* hydrochloric acid, pH 7.4 (15 μmoles) and 0.1 ml. of cell suspension were in a total volume of 3.5 ml. Further additions were made as follows: 6.6 μmoles of calcium chloride; 0.39 μmoles of pentachlorophenol, and 5.0 μmoles of potassium phosphate, pH 7.4. Oxygen consumption was measured with a Clark type oxygen electrode. PCP, pentachlorophenol; Pi, inorganic phosphate.

Fig. 2. Effect of pentachlorophenol on calcium ion-free respiration. *Tris* hydrochloric acid, pH 7.4 (15 μmoles) and 0.15 ml. of cell suspension were in a total volume of 3.5 ml. Further additions were 0.39 μmoles of pentachlorophenol; 3.5 μmoles sodium phosphate, pH 7.5; 20 μmoles of potassium chloride, and 1.5 μmoles of calcium chloride.

Fig. 3. Effect of pentachlorophenol on respiration inhibited by calcium ions in phosphate buffer. Potassium phosphate, pH 7.4 (5.0  $\mu$ moles) and 0.15 ml. of cell suspension were in 3.5 ml. Additions were 3.3  $\mu$ moles of calcium chloride and 0.39  $\mu$ moles of pentachlorophenol.

It seems that pentachlorophenol is not a bacterial equivalent of dinitrophenol or an oligomycin-type inhibitor in the mitochondrial system.

## PATHOLOGY

### Increase of Lysosomal Enzymes in Skin Cancers

THE function of the lysosome in the pathogenesis of cancer is unknown. In the normal cell these cytoplasmic structures bound to the membrane are thought to be constituents of an intracellular digestive system. Exogenous material that will eventually be digested is engulfed by a cell membrane<sup>1</sup>. These newly formed lysosomes are thought to be long lived structures involved in numerous digestive events.

Lysosomes are also important after normal cells are injured or die. Hydrolytic enzymes are released and distributed throughout the cell. Lysosomal enzyme activities greatly increase. After cellular death the pH of the cell is probably lowered to quantities where lysosomal enzymes have their maximal activity. Rapid cell autolysis and tissue breakdown ensue. Lysosomal enzymes are markedly increased concomitant to uterine involution, resorption of tadpole tails during metamorphosis, and in rheumatoid synovial tissue<sup>2-4</sup>. The cancer process is a steady invasion and erosion of normal tissue, and so an increase of lysosomal enzyme activity can be anticipated.

In this investigation 90 ICR Swiss female mice, 50-55 days old, were divided into three groups: the shaved skin of the back was exposed once to 0.125 mg of 7,12-dimethylbenzanthracene (DMBA) in acetone; after three weeks 0.25 ml. of 0.033 per cent of the tumour promoter, croton oil in acetone, was applied daily for 19 weeks; a second group of thirty mice received only DMBA; the third group received daily 0.25 ml. of 0.01 per cent of the complete carcinogen, 3-methylcholanthrene in acetone, for 22 weeks.

The number and distribution of tumours were noted weekly. After 22 weeks, all tumours were graded according to size and location. Application of carcinogens was halted. In mice given the DMBA and croton oil the progress of regression of the papillomas and the number of cancers in the mice treated with 3-methylcholanthrene were observed for an additional 6 weeks. Differences between complete carcinogenesis and tumour promotion are summarized in Table 1.

Table 1. DIFFERENCES BETWEEN TUMOUR PROMOTION AND COMPLETE CARCINOGENESIS

Group	Number of papillomas			No. of cancers 28 weeks
	19 weeks	22	28	
DMBA and croton oil	132	127	54	9
3-Methylcholanthrene	34	95	18	71
DMBA only	0	0	0	0

After 28 weeks, several of the skin cancers, untreated skins (DMBA only) and untreated mouse livers were ground with 10 parts by volume of 0.09 per cent sodium chloride to 1 part of tissue by weight with a hand homogenizer. Skin is difficult to homogenize and the lysosomal particles would be damaged, and so no attempt was made to differentiate between bound and free enzyme activities. Four frozen rat livers from 60-day-old rats and an adult pheasant liver were similarly homogenized. Acid phosphatase,  $\beta$ -glucuronidase and cathepsin activities were measured using standard enzyme assays<sup>5-7</sup>. Proteins were determined by the method of Lowry<sup>8</sup>.

Table 2. LYSOSOMAL ENZYME ACTIVITIES IN SKIN CANCERS AND NORMAL TISSUES

Tissue	Cathepsin ( $\mu$ moles of tyrosine/mg of protein/h)	$\beta$ -Glucuronidase $\mu$ moles of phenolphthalein/ mg of protein/h $\times 10^{-3}$	Acid phosphatase nmoles of nitrophenol/mg of protein/h
Mouse skin (DMBA)	(10) 0.0	(10) 0.0	(7) 15.8 $\pm$ 2.6
Mouse skin cancer	(10) 0.41 $\pm$ 0.04	(9) 1.5 $\pm$ 0.25	(9) 26.0 $\pm$ 4.8
Mouse liver	(10) 0.41 $\pm$ 0.08	(10) 0.81 $\pm$ 0.2	(10) 42.0 $\pm$ 8.0
Rat liver	(4) 0.05 $\pm$ 0.004	(4) 3.2 $\pm$ 1.7	(4) 27.1 $\pm$ 3.3
Pheasant liver	(1) 0.85	(1) 0.3	(1) 46.6

Lysosomal enzyme activity greatly increased in skin cancers (Table 2). Mouse skin cancer cathepsin,  $\beta$ -glucuronidase, and acid phosphatase activity were enhanced to a degree comparable with those found in liver which is an organ noted for its great metabolic activity. No cathepsin or  $\beta$ -glucuronidase activity was detected in skin initiated only with DMBA. Nearly 74 per cent of the papillomas induced by 3-methylcholanthrene became cancers (Table 1). Fifty-nine per cent of the papillomas induced by croton oil regressed. No cancers were observed. Forty-nine of the papillomas induced by croton oil remained the same size. Only five of the 132 croton oil papillomas increased in size.

The skin chemical carcinogenic process may be divided into three distinct stages: the original insult to the cell resulting in papillomas, regression of the papillomas or conversion of the papillomas to cancers, and finally growth and maintenance of the cancers.

The original insult to the cell by the carcinogen can result from a disturbance of the digestive function of the lysosome by the carcinogen. In addition, initial damage could be attributed to peroxidation of the lysosomal lipid membrane prematurely releasing hydrolytic enzymes. These two possibilities are not necessarily mutually exclusive. Several carcinogens have been added to HeLa cells<sup>9</sup>, and all those tested appeared first in the lysosomes. Many undigestible particles may accumulate in the lysosome, and so the function of digestion in the lysosome could be impaired. Chemically induced carcinogenesis is a cumulative process which apparently reaches a threshold before tumours form. The first tumours do not appear until carcinogens are applied daily for 5-10 weeks. Progressive accumulation of undigestible carcinogen residues may overwhelm the lysosome, making it unable properly to eliminate its wastes.

Antioxidants protect lipid membranes from peroxidation<sup>10</sup>. Premature damage of the lipid membrane by peroxidation may release hydrolytic enzymes which damage other cellular functions. Several peroxy compounds are carcinogenic<sup>11</sup>. A hydroperoxide of cholesterol is carcinogenic in certain conditions<sup>12</sup>. Peroxidation may change the geometrical isomerism of the unsaturated fatty acids present in the lipid membrane<sup>13</sup>. Permeability of the lysosomal membrane to various biological fluids may be altered. Changes of the hormonal control of the lysosomal membrane may result. If antioxidants are applied simultaneously with croton oil, the incidence of skin papillomas is greatly reduced<sup>14</sup>. Hydrocortisone, a protector of lipid lysosomal membranes, regresses skin tumours<sup>15</sup>. The early reactions of carcinogenesis may be different from events which determine the fate of the early papilloma. Lysosomes may be involved in other stages of carcinogenesis.

Lysosomes are probably important in the fate of the papilloma. Differences between tumour promotion and complete carcinogenesis could be attributed to changes in the hormonal control of the lysosomal membrane (Table 1). In regressing tissues lysosomal enzyme activity is enhanced. Lysosomal enzyme activity is also increased in regressing Flexnor-Jobling tumours<sup>16</sup>. Hormonal control of the lysosomal membrane apparently remains effective in most tumour tissues induced by croton oil. In pre-cancer papillomas, however, hormonal control of the lysosomal membrane can be lost. These papillomas do not regress, but are transformed into cancers.

The early metabolic changes of carcinogenesis and critical reactions important in the fate of the early papilloma could be different from the cellular changes necessary for growth and maintenance of skin cancers. Lysosomal enzyme activities are greatly elevated in the growing cancer (Table 2). The intense enzyme activity at this stage of carcinogenesis could be important in the invasion and destruction of normal tissue or this great enzyme activity may indicate rapidly metabolizing tissue.

### Phagocytic Activity after Thymectomy

In recent years it was shown that thymectomy soon after birth causes impairment of the immune response of the mature animal. A depression of antibody production was reported in mice<sup>1</sup>, rats<sup>2</sup>, rabbits<sup>3</sup> and guinea-pigs<sup>4</sup>, and a depression of the homograft reaction was observed after thymectomy<sup>5</sup>.

This lack of immunological response has usually been related to the depletion of lymphoid tissues associated

with early thymectomy<sup>5</sup>, although the role of lymphocytes in immunological responses seems to be poorly understood.

Comparatively little attention has been paid to the changes induced by thymectomy in the macrophage system, which is known to be involved in immunological reactions<sup>6-8</sup>.

It was shown by Miller and Moreman<sup>9</sup>, Osoba and Miller<sup>10</sup> and Miller and Howard<sup>11</sup> that mice thymectomized at birth exhibit moderate to marked reticuloendothelial cell hyperplasia and increased phagocytic activity (as measured by the clearance from the blood of colloidal carbon). Experiments by Morrow and Di Luzio<sup>12</sup>, however, did not show any apparent abnormality in the granulopoietic activity of the thymectomized rats: colloidal carbon removal from the blood after a single intravenous injection of 8 mg/100 g body weight occurred at about the same speed both in thymectomized and in sham-operated animals.

Two or three day old Wistar albino rats were thymectomized according to the method of Miller<sup>13</sup>. At 5 weeks of age, the phagocytic activity in the thymectomized animals was evaluated by measuring the rate of removal from the blood of colloidal carbon (*C* 11/1431 *a*). Sixteen milligrams of carbon per 100 g body weight were injected intravenously and blood samples of 0.01 ml. were obtained from the tail veins and haemolysed in 0.1 per cent sodium carbonate. The carbon concentration was estimated spectrophotometrically at 650 m $\mu$  and the granulopoietic index  $K$  ( $\log C_0 - \log C_{30}/30$  min) and the half-time ( $t/2$ ) were calculated. The absence of thymic residues was verified in all cases. For comparison the rate of removal of carbon was estimated in normal animals of the same age and body weight: previous experiments demonstrated that controls behave like unoperated animals.

After a single intravenous injection of carbon no difference could be detected in thymectomized and normal rats. If another dose of 16 mg was injected intravenously after 1 h, the velocity of carbon removal was reduced in normal animals and was very appreciably increased in the thymectomized ones (Table 1, Fig. 1).

Fig. 1. Colloidal carbon removal from blood after an intravenous injection of 16 mg/100 g body weight (each curve represents the average results of six experiments). ●—● Normal rats; only one dose was given. ○—○ Normal rats; the experiment was carried out 1 h after the injection of an equal dose by intravenous route. ■—■ Thymectomized rats; one dose. □—□ Thymectomized rats; the experiment was carried out 1 h after an equal dose by intravenous route.

Fig. 2. Colloidal carbon removal from blood after an intravenous injection of 16 mg/100 g body weight. The experiment was carried out 24 h after the injection of an equal dose by intraperitoneal route (each curve represents the average results of six experiments). ●—●, Normal rats. ■—■, Thymectomized rats.

Further experiments were carried out with an intraperitoneal injection of 16 mg of carbon followed by an intravenous injection of the same dose 24 h later. The velocity of carbon removal was higher in the thymectomized animals (Table 1, Fig. 2).

Table 1. COLLOIDAL CARBON REMOVAL FROM BLOOD OF THYMECTOMIZED AND NORMAL RATS AFTER ONE INTRAVENOUS INJECTION OF 16 mg

	Without a previous dose	1 h after dose (intravenous)	24 h after dose (intraperitoneal)
	K	K	K
Thymectomized	0.014 19 ± 0.003 ± 5.56	0.038 7 ± 0.013 ± 2.44	0.043 9 ± 0.010 ± 2.37
Normal	0.019 17 ± 0.002 ± 5.19	0.009 32 ± 0.002 ± 6.85	0.022 12 ± 0.005 ± 2.23

Values are expressed as means ± standard errors. There were six animals in each group.

Differences between thymectomized and normal animals that were not given a previous dose are not significant. Differences are significant ( $P < 1$  per cent or even  $< 1$  per mil.) in the other cases, when a previous dose was given (by intravenous or intraperitoneal route).

Histological investigations showed appreciable hyperplasia of reticuloendothelial cells in the spleen and in the lymph nodes.

It appears that the phagocytic response to stimulation by colloidal suspensions is much higher in thymectomized rats because a larger number of macrophages is involved and possibly because a larger amount of particles is ingested by single macrophages. The velocity of carbon removal from the blood may not be appreciably affected after a single injection, but it is very different, in comparison with normal animals, after repeated injections. The features of the reticuloendothelial system (RES) seem to be very similar in rats and mice after thymectomy; the difference may be only quantitative.

It seems difficult to correlate the reticuloendothelial hyperplasia and the lymphatic depletion with the decreased immune response after thymectomy; in fact the close relationship between the RES, the lymphocytes and the formation of antibodies is still obscure even in normal animals.

Miller and Howard<sup>11</sup> suggest that early thymectomy first induces lymphatic depletion and immunological incompetence; reticuloendothelial cell hyperplasia could

be the result of infection with some virus to which immunologically defective animals may be more susceptible. They pointed out that in spite of the similarity between the graft versus host disease and the neonatal thymectomy syndrome, there is no unequivocal evidence for the operation of autoimmune processes, while experiments with thymectomized germfree mice<sup>14</sup> strongly suggest that cell proliferation (along with destructive lesions) is triggered by some environmental influence.

The possibility that the reticuloendothelial cell hyperplasia is the counterpart of lymphoid aplasia and that both events are contemporarily induced by thymectomy, however, is not excluded.

## Autoradiography of Rat Lung before and after Birth

THE details of the development of the mammalian lung from late foetal life to maturity are still little known. For several decades many investigators have thought that proliferation in the mammalian alveolar epithelium stops in late foetal life; and that the epithelium then undergoes degeneration and desquamation before birth<sup>1-4</sup>. Bertalanffy and Leblond, using a colchicine technique and classical histological methods, showed in 1953 that the alveolar lining cells in adult rat lung are continuously renewed, just as the surface cells of the intestine and skin. Since then, high resolution autoradiography with tritiated thymidine has been applied to the study of cellular proliferation in adult mice and rats. The rates of cellular proliferation of lung tissue have not been studied in the late foetal or neonatal period either with autoradiographic or colchicine techniques. In order to obtain more information on the proliferative properties of lung in the late foetal and early neonatal periods we undertook an *in vitro* autoradiographic study of the rat lung.

The lungs of four rat foetuses and those of three newborn rats were used. The foetuses were removed from the uterine horn under ether anaesthesia on the seventeenth (two foetuses) and on the nineteenth (two foetuses) days of gestation. The newborn rats were killed 6 h after birth. All animals were killed by decapitation.

Immediately after removal from the thorax, the lungs were cut into small pieces, each approximately 0.1–0.2 cm thick and 0.3 cm in diameter. The slices of lung were incubated in 100 ml. of Ringer's solution containing 100  $\mu$ c. of tritiated thymidine (specific activity 3.0 c./mmole). A mixture of gas composed of 95 per cent oxygen and 5 per cent carbon dioxide was bubbled through the incubation medium for 2.5 h at a rate of flow sufficient to

keep the tissue slices in constant motion. After incubation, the tissues were washed for 2 min each in three 100 c.c. portions of Ringer's solution and fixed for 24 h in neutral 10 per cent formaldehyde solution. After embedding in paraffin, sections were cut from each side of the block at  $5\mu$  to a depth of  $150\mu$ . The slides were deparaffinized, rehydrated, and dipped in NTB<sub>2</sub> 'Kodak' emulsion. The dipped slides were exposed for 4 weeks in a Conrad-Joffe fluid emulsion autoradiography system in a carbon dioxide atmosphere and at a relative humidity below 15 per cent. They were then developed, using 'Kodak 19' developer (3 min), 'Kodak SB5a' stop bath (15 sec), and 'Kodak' acid fixer (twice clearing time). All solutions were maintained at 18° C throughout development. The developed slides were washed for 12–18 h, stained with haematoxylin and eosin, dehydrated and maintained in balsam. The percentage of labelled cells was determined by counting 4,000 cells randomly scattered in areas of lung in each age group. In addition, the number of labelled alveolar lining cells was counted in 1,000 randomly selected alveolar spaces in the foetal and neonatal lungs. This latter procedure was necessary because of the well known flattening of alveolar cells after some hours of respiration. The background count was low and random. The results are shown in Table 1. The percentage of labelled cells was the same in the 17 and 19 day old foetal lungs, and the results were therefore tabulated together. In all the rats studied there was marked uptake of tritiated thymidine in the alveolar epithelium before (6.7 per cent) and after birth (estimated 4.02 per cent). There was a marked reduction in labelling of stromal cells (from 8.9 per cent to 4.0 per cent) after birth. The muscular and fibrous elements of the intrapulmonary branches of the pulmonary artery showed the same labelling in the foetal and early neonatal period. It is interesting to note that the columnar bronchiolar epithelium had an increased number of labelled cells after birth (from 4.8 per cent to 5.4 per cent).

Table 1. LABELLING OF CELLS IN RAT LUNG IN THE LATE FOETAL AND EARLY NEONATAL PERIOD

	Alveolar epithelium (per cent)	No. of labelled alveolar cells/1,000 alveolar spaces	Stroma (per cent)	Respiratory epithelium (per cent)	Pulmonary artery (intrapulmonary branches) (per cent)
Foetal lung (17–19 days of gestation)	6.7	578	8.9	4.8	7.1
Lung (6 h after birth) calculated	4.02	335	4.0	5.4	7.2

The embryological development of mammalian lung has been extensively investigated with classical histological methods. In the past few decades a number of investigators have expressed the view that the mammalian alveolar lining cells do not proliferate in late foetal life, that they degenerate and desquamate up until the time of birth. Short<sup>1</sup> believed that alveolar epithelium was not present in man and guinea-pig after birth. Three years later, Low demonstrated by electron microscopy the presence of continuous alveolar epithelium in the adult mammalian lung<sup>2</sup>. In the same year, Bertalanffy and Leblond demonstrated the continuous renewal of alveolar cells under physiological conditions<sup>3</sup>. They estimated that the percentage of alveolar tissue undergoing mitosis at any single time was between 0.63 and 1.23 per cent in the adult rat and suggested that the cell surplus is excreted with the tracheal secretions. The labelling index of alveolar lining cells and of bronchial epithelium in adult rats and mice was first determined with autoradiography by Schultze in 1960 (ref. 7) and was 1.8 per cent and 1.0 per cent, respectively. Shorter and Titus found a labelling index of 0.25 to 1.0 per cent for alveolar epithelium in the adult mice with autoradiography<sup>8</sup>. The labelling index of bronchial epithelium similarly determined in adult mice was found to be

0.53–1.72 per cent by Meyer zum Gottesberge and Koburg<sup>9</sup>. The kinetics of cell proliferation were studied autoradiographically in 20 day old rat fetuses by Wegener and associates<sup>10</sup>, who demonstrated a placental barrier to tritiated thymidine. The grain count in each nucleus was significantly lower in the foetal than in maternal tissues, including the foetal and maternal sides of the placenta. They found no diurnal variation in the rate of proliferation of different foetal tissues. The lack of variation in the mitotic index of foetal tissues over a period of 24 h is in agreement with the observations of Aschoff<sup>11</sup>, who found no diurnal rhythm in mammalian fetuses and newborn infants. Because of the placental barrier for tritiated thymidine, we feel that *in vitro* labelling is the best method to study cellular proliferation in foetal tissues.

Fig. 1. Lung of newborn rat. Alveolar epithelial cells labelled with tritiated thymidine. ( $\times 804$ .)

Our investigation showed a marked decrease in the proliferative rate of alveolar epithelium (about 40 per cent) and of stromal cells (45 per cent) after birth. If our results are compared with those of other investigators, the proliferative rate of alveolar lining cells is about twice the rate of that of adult animals in the neonatal, and about three times the rate of adults in the late foetal, periods. The increase of proliferation of respiratory epithelium (from 4.8 to 5.4 per cent) after birth is in agreement with the observations of Broman<sup>12</sup> in the cow and man, and of Willson<sup>14</sup> in the mouse, who demonstrated that the number of bronchial lining cell divisions between the trachea and alveolar ducts increased between birth and maturity. The appearance of surfactant has been found to take place about the same time as the beginning of the desquamation of cells in the foetal lung. A surfactant material may therefore be derived from the desquamated cells and the continued loss of cells throughout life may provide a constant source of this material<sup>13</sup>.

The development of rat lung from birth to maturity is at present being studied by the foregoing method. These anatomical data are necessary for the better understanding of various physiological and pathological processes during development.

Future investigations should also be directed toward problems of lung pathology. High resolution autoradiography with tritiated thymidine, by an *in vitro* technique, should be used to study degenerative, neoplastic and inflammatory lung diseases of man. Fresh human surgical material is readily available, the technique is simple, and the equipment necessary is not expensive. Such investigations would provide important new data for the understanding of diseases of the lung.

## IMMUNOLOGY

### Immunological Reactivity of Lymphocytes in Multiparous Females after Strain Specific Matings

It is now established that multiple interstrain matings may change the immunological reactivity of the female towards the foreign isoantigens of the mating male. This altered reactivity of post-partum females has been investigated in transplantation as well as serological experiments. The results of the two modes of investigation are, however, contradictory. The transplantation experiments have, with one exception<sup>1</sup>, shown a decreased<sup>2-6</sup> or unaltered<sup>7,8</sup> reactivity of the post-partum females against the transplantation antigens of the mating male. Serological investigations, on the other hand, have indicated sensitization of the females after interstrain matings. Haemagglutinins directed towards the antigens of the mating male have been demonstrated in the sera of outcrossed, multiparous females<sup>1,9,10</sup>. These conflicting results could be explained by the assumption that immunological enhancement<sup>11</sup> is responsible for the prolonged survival of tissues in the transplantation experiments. Kaliss and Dagg<sup>1</sup> investigated this hypothesis. Some of their results supported the enhancement hypothesis, but no enhancing effect of serum from multiparous females could be demonstrated after transfer to virgin mice of the maternal strain.

If enhancement were responsible for the decreased resistance of multiparous females to homografts from the mating male, it would then be impossible to detect cell-bound immunity by experiments in which homografts from the mating male are transplanted to these multiparous females. In the spleen assay technique of Simonsen<sup>12</sup> the degree of cell-bound immunity can be measured in a test system where the effect of cell-bound immunity is separated from the effect of humoral antibodies. Simonsen's spleen assay technique has therefore been used in the present work to determine whether cell-bound immunity, directed against the antigens of the mating male, does exist in multiparous females.

Newborn hybrid mice, established by crossing the strains of the female and the mating male, were injected with lymphoid cells from the outcrossed females and the ability of those cells to induce a graft versus host reaction was studied. The working hypothesis was that if the maternal lymphoid cells were sensitized against the transplantation antigens of the mating male, they should

induce a more severe graft versus host reaction, and thus cause a higher spleen index, than that induced by lymphoid cells from virgin females.

Female mice of the inbred strain *CBA* were divided into four groups and females of the strain *C57BR/cd* into three groups. *A* (experimental group): *CBA* or *C57BR/cd* females were mated to males of the inbred strain *A/Sn*; *B* (control group): *CBA* females were mated to *CBA* males; *C* (control group): *CBA* or *C57BR/cd* females were retained as virgins; and *D* (control group): *CBA* or *C57BR/cd* females were immunized against *A/Sn* tissue by inoculation at 2-week intervals (two to four times) with 0.5 ml. of a crude saline suspension of spleen, liver and lymph node cells from two *A/Sn* female mice.

Two weeks to two months after they had delivered the last of their litters, the females were killed; their spleens and lymph nodes were processed through a 60 mesh steel screen and suspended in physiological saline. Fifteen million cells in 0.2 ml. were injected intraperitoneally into (*CBA* × *A/Sn*)*F*<sub>1</sub> and (*C57BR/cd* × *A/Sn*)*F*<sub>1</sub> mice respectively, which were less than 6 days old. In each litter, consisting of at least six animals, one or more animals were injected with 15 million lymphoid cells from either: females mated to *A/Sn* males; females mated intra-strain; virgin females, or females actively immunized against *A/Sn* transplantation antigens. One or more animals in each litter were not injected and served as controls for the calculation of the spleen index.

Eight days after injection the animals were weighed and killed; the spleens were removed and also weighed. The spleen index for each animal injected with lymphoid cells from females of the experimental and control groups was calculated according to Simonsen<sup>12</sup>, relating the spleen and body weights of the experimental animals to the spleen and body weights of the control animals.

The results are shown in Tables 1 and 2. Table 1 shows that the mean spleen index obtained after injecting (*CBA* × *A/Sn*)*F*<sub>1</sub> hybrids with lymphoid cells from *CBA* females, mated intra-strain (group *B*), is the same as that obtained by injection of lymphoid cells from virgin females (group *C*). These spleen indices differ significantly from those caused by injection of lymphoid cells from females actively immunized against the transplantation antigens of the *A/Sn* strain (group *D*).

In the case of *CBA* females mated one to four times with *A/Sn* males, the immunological reactivity of the lymphoid cells of the females against the antigens of the mating male is increased with an increased number of pregnancies; the means of the spleen indices increase from 1.45 to 1.91 after one to four pregnancies. The mean of the spleen index for group *A4* differs from those of groups *B* and *C* (*P* < 0.05). When *C57BR/cd* females are mated to *A/Sn* males the immunological reactivity becomes significantly increased after one pregnancy (Table 2). Group *C* differs

Table 1. MEAN SPLEEN INDICES OF (*CBA* × *A*)*F*<sub>1</sub> ANIMALS INJECTED WITH 15 MILLION LYMPHOID CELLS FROM OUTCROSSED *CBA* FEMALE MICE OR *CBA* FEMALES OF THE CONTROL GROUPS

Source of lymphoid cells	No. of hybrid animals injected	Mean spleen index	Standard error
<i>CBA</i> females mated to <i>A/Sn</i>			
Four litters (group <i>A4</i> )	10	1.91	± 0.113
Three litters (group <i>A3</i> )	13	1.57	± 0.137
Two litters (group <i>A2</i> )	12	1.45	± 0.137
One litter (group <i>A1</i> )	10	1.45	± 0.119
<i>CBA</i> females mated to <i>CBA</i> (group <i>B</i> )	36	1.55	± 0.065
<i>CBA</i> virgins (group <i>C</i> )	38	1.56	± 0.055
<i>CBA</i> females immunized against <i>A/Sn</i> (group <i>D</i> )	33	2.04	± 0.098

Table 2. MEAN SPLEEN INDICES OF (*C57BR* × *A*)*F*<sub>1</sub> ANIMALS INJECTED WITH 15 MILLION LYMPHOID CELLS FROM OUTCROSSED *C57BR* FEMALE MICE OR *C57BR* FEMALES OF THE CONTROL GROUPS

Source of lymphoid cells	No. of hybrid animals injected	Mean spleen index	Standard error
<i>C57BR</i> females mated to <i>A/Sn</i>			
Four litters (group <i>A4</i> )	9	2.10	± 0.174
Three litters (group <i>A3</i> )	14	1.90	± 0.102
Two litters (group <i>A2</i> )	12	1.95	± 0.077
One litter (group <i>A1</i> )	19	1.87	± 0.116
<i>C57BR</i> virgins (group <i>C</i> )	25	1.57	± 0.069
<i>C57BR</i> females immunized against <i>A/Sn</i> (group <i>D</i> )	14	2.62	± 0.161

from groups A4 and A2 ( $P < 0.01$ ) and from groups A3 and A1 ( $P < 0.05$ ). These results (Tables 1 and 2) indicate that, after interstrain matings, the maternal lymphoid cells become sensitized against the isoantigens of the mating male.

The standard errors of the mean spleen indices are rather high (Tables 1 and 2). It is of interest to establish if this is due to technical errors or if there is a true variation in the occurrence and degree of immunization after multiple pregnancies. Such a variation might be expected if the immunization was a result of a chance phenomenon, as for example occasional pathological leakage of the placenta. This question was investigated by comparing the variances of the experimental and control groups. The standard deviation of the spleen indices from animals injected with lymphoid cells from virgin females was considered to represent the methodological error. The variance of this group was compared with the variances of each of the experimental groups by using the  $F$  test. In only one case, when CBA females were mated interstrain three times, was there a larger variance ( $P < 0.05$ ) in the experimental than in the control group. Evidently, the immunization was not subject to any individual variation greater than the methodological error and therefore the immunization seems to be a regularly occurring phenomenon in interstrain pregnancies.

The results of the present investigation indicate that cell-bound immunity, directed against the isoantigens of the mating male can be induced in CBA and C57BR/cd female mice by mating these females to males of the strain A/Sn. This finding supports the results of earlier serological investigations<sup>1,9,10</sup> in showing that outcrossed females become sensitized against isoantigens of the mating male. Whether this means that enhancement is responsible for the prolonged survival of homografts from the mating male in outcrossed multiparous females cannot be concluded from this work. There must, however, be some mechanism which makes the cell-bound immunity, demonstrable with the technique used in this work, ineffective in the rejection of transplants from the mating male, and one plausible explanation is that humoral antibodies may interfere with the homograft reaction.

### Inhibition of the Mitogenic Factor in Phytohaemagglutinin by an Antiserum

EXTRACTS of some varieties of the bean *Phaseolus vulgaris* can agglutinate erythrocytes<sup>1</sup>, precipitate human cell homogenates and serum proteins<sup>2</sup>, stimulate mitosis in leucocytes<sup>3</sup>, alter the sensitivity of leucocytes to cytotoxic agents and radiation<sup>4,5</sup>, and stimulate leucocytes *in vitro* to produce gamma globulin<sup>6</sup>. A commercially prepared extract of *Phaseolus vulgaris*, derived according to the method of Rigas and Osgood<sup>7</sup>, is available as phytohaemagglutinin (PHA-M, Difco Laboratories, Detroit,

Michigan). This preparation, which is apparently a mixture of proteins<sup>8</sup>, is frequently used as a mitogenic agent for *in vitro* leucocyte cultures. Some of its antigenic properties have already been reported<sup>9</sup>.

Sensitivity to other antigens, such as PPD, diphtheria toxoid, pertussis vaccine, or penicillin, is attended by this mitogenic response of cultured leucocytes to addition of the appropriate antigen<sup>10,11</sup>. Antibodies may stimulate mitosis; a leucocyte antiserum produced an increased mitosis in a leucocyte culture<sup>12</sup>. Extracts of pokeweed (*Phytolacca americana*) have been used as a mitogenic agent<sup>13</sup>; however, none of these agents produces the high mitotic rates that are consistently obtained with PHA.

The mechanism of action of the leucocyte mitogenic factor in PHA is not known, but various suggestions have been made. Beckman proposes that it acts by precipitating a mitogenic inhibitor in serum<sup>2</sup> while Gräsbeck indicates that it attaches to the leucocyte, thereby initiating mitosis<sup>12</sup>. Nowell suggested that the mitogenic factor acted on the cell surface to permit the entrance of materials needed for cell replication<sup>3</sup>. Hastings *et al.* concluded that the mitogenic action depended on the agglutination of the leucocytes<sup>14</sup>.

The objective of the present investigation was the production in rabbits of an antiserum to PHA-M that could be used to study the mechanism of action of PHA-M in leucocyte cultures.

Four adult white female rabbits were injected intravenously with 0.5–1.0 ml. of reconstituted Difco PHA-M three to five times each week initially for a period of 4 weeks. Throughout the experiment, litter mates from the same hutch were used as controls and were not given injections of PHA-M. Before, during, and after the immunizing phase of this experiment, blood samples were removed from the ear veins of all rabbits. The serum and cells were rapidly separated and the former promptly refrigerated. In a system of immunoelectrophoresis designed to detect the presence of anti-PHA-M antibodies in the serum of the injected rabbits, distinct precipitin bands were produced by the serum withdrawn from the injected rabbits 28 days after the commencement of PHA-M injections. When the antiserum was placed in the central well and the PHA-M in the lateral troughs, three definite precipitin bands were formed in the globulin region of the agar coated slide. By reversing the positions of the antiserum and PHA-M, six major precipitin bands were produced (Fig. 1). No precipitin bands were formed by the sera of control rabbits at any time, nor were precipitin bands formed by the sera of the injected rabbits during the control phase of the experiment.

The globulin fractions of the rabbit sera which contained antibody were precipitated by mixing equal volumes of antisera and of a 27.2 per cent solution of sodium sulphate. After standing for 10 min in a water bath at 37° C, the mixture was centrifuged for 10 min at 3,500 r.p.m. After discarding the supernatant, the precipitant

Fig. 1. Photograph of immunoelectrophoretic slide. Centre well contained PHA-M. Lateral trough without precipitin bands contained control rabbit globulin extract. Lateral trough showing precipitin bands contained rabbit anti-PHA-M globulin extract.

was reconstituted to the original volume with water. This procedure did not reduce the effectiveness of the antibody.

To determine the effect of this newly derived antibody on the mitogenic factor in phytohaemagglutinin, seven series of human peripheral leucocyte cultures from four donors (each series from a common donor) were initiated according to the method devised by Moorhead *et al.*<sup>15</sup>. The standard cultures contained 2 ml. of normal plasma with 5,000–10,000 leucocytes/mm<sup>2</sup>; 8 ml. of medium 199; 0.3 ml. of PHA-M; 1,000 u of penicillin and 5 mg of streptomycin in 0.1 ml. of saline. The constituents of the experimental cultures were identical except for the mitogenic factors. They were prepared by incubating 0.3 ml. of PHA-M for 3 h at 37° C with (1) saline, (2) graded volumes of control rabbit serum, (3) graded volumes of rabbit anti-PHA-M serum, and (4) graded volumes of the rabbit anti-PHA-M serum globulin extract. After incubation, these mixtures were centrifuged at 3,500 r.p.m. for 10 min, and the resulting supernatant solutions were used as source of carriers of mitogenic factors in place of direct addition of 0.3 ml. PHA-M. These four forms of mitogen were the only variables introduced into this series of cultures. After the cultures were incubated for 72 h, colchicine was added to a final concentration of 10<sup>-6</sup> moles/l. and the incubation continued for a further 4 h. The cells were then separated by centrifugation and resuspended in hypotonic (0.7 per cent) sodium citrate for 40 min as a preliminary to fixing in acetic acid, orcein staining, and squashing.

Both the injected rabbit antiserum and the globulin fraction extracted from it suppressed the mitogenic activity of the PHA-M in leucocyte cultures (Table 1). Addition of the supernatant from the incubation of larger amounts of the antiserum with PHA-M completely suppressed mitosis in the experimental cultures. When the supernatant from the incubation of the control rabbit serum and PHA-M was added the mitotic rate was as high as that in the saline control cultures. Addition of the antiserum to control cultures after culture initiation, however, did not completely inhibit leucocyte mitosis. The haemagglutinating factor was still present in the supernatant of the antiserum-PHA-M mixture even though the mitogenic factor had been completely inactivated.

Table 1. EFFECT OF RABBIT ANTISERUM TO PHYTOHAEMAGGLUTININ ON THE MITOGENIC FACTOR AS DEMONSTRATED IN HUMAN PERIPHERAL LEUCOCYTE CULTURES\*

\* The standard control culture consisted of 2 ml. plasma with suspended leucocytes, 8 ml. media 199, penicillin, streptomycin, and 0.2 ml. PHA-M.

† The globulin extract was reconstituted to initial rabbit serum volume with distilled water.

‡ This animal developed severe otitis and did not receive PHA-M injections for 1 month before serum was taken for this experiment.

§ Non-immunized litter mate from the same hatch.

Fig. 2. Photomicrograph showing fluorescence of leucocytes exposed to PHA-M and anti-PHA-M globulin extract tagged with fluorescein isothiocyanate

In an effort to trace the distribution of PHA-M in cultured cells throughout the proliferative phase, fluorescein tagged antiserum was prepared according to a modification of the method of Riggs<sup>16</sup>. Six milligrams of fluorescein isothiocyanate in 1.5 ml. acetone was added to a suspension of 4 ml. rabbit antiserum to PHA-M, 16 ml. saline, 3 ml. carbonate-bicarbonate buffer (0.5 molar, pH 9), and 2 ml. acetone. After stirring in the cold for 18 h, this preparation was dialysed for 24 h against 0.1 molar sodium chloride buffered with sodium phosphate (pH 7.2), with at least three changes of dialysate buffer. The resulting conjugated antiserum was quickly frozen and stored for later use; control rabbit sera were also conjugated in the same manner.

Cultures were again set according to the method of Moorhead using leucocytes from a common donor and dispensing equal volumes of well mixed leucocyte rich plasma into each culture bottle. In this series, 0.2 ml. of PHA-M was used as the mitogenic agent in all cultures except for several control cultures which contained no phytohaemagglutinin. Cultures were interrupted at predetermined times throughout the 72 h period of growth. The cells were collected by centrifugation, smeared on microscope slides (in the manner of peripheral blood smears), fixed for 45 sec in cold methanol-formalin (90 ml. absolute methanol, 10 ml. 40 per cent formalin) leucocyte fixative, rinsed in cold saline and dried in air. Slides selected from each time interval were then placed in a Coplin staining jar containing fluorescein tagged anti-PHA-M serum; identical slides were placed in a Coplin jar containing tagged control rabbit serum. The slides were left in the Coplin jars overnight at a temperature of 6° C, then were removed and rinsed three times in normal saline, mounted in buffered glycerine and kept refrigerated until they were observed under an ultra-violet microscope. Eight to twelve per cent of the cells from an experimental culture (containing PHA-M) interrupted after incubation for 1 h fluoresced a characteristic apple green colour (Fig. 2) if they were exposed to the tagged anti-PHA-M serum. If identically cultured cells were exposed to the tagged control serum, there was no fluorescence. No fluorescence occurred when the cells placed in a control culture (containing no PHA-M) were exposed to the tagged anti-PHA-M serum. The percentage of tagged cells slowly increased until incubation reached 72 h at which time 45–68 per cent of the cells tagged.

In a previous investigation, which used a directly conjugated phytohaemagglutinin as the mitogenic agent, Michalowski *et al.*<sup>17</sup> reported that a majority of the cells fluoresced as early as 4–9 h. That procedure, however, did not rule out the possibility of the living lymphocytes preferentially phagocytosing the fluorescein-conjugated PHA. It would seem that our technique is more definitive because the fluorescein-conjugated antiserum is not introduced until after the cells have been cultured and fixed.

From the preceding data, it appears that the mitogenic factor which is present in phytohaemagglutinin does have antigenic properties because its antiserum does have an inhibitory effect on the mitotic rate of the cultured cells. Inhibition of cell growth as measured by the mitotic rate was found to be directly proportional to the amount of anti-PHA-M incubated with phytohaemagglutinin. Although the procedure for tagging with fluorescein does not permit localization of the primary site of action of phytohaemagglutinin, this procedure does permit enumeration of the cells altered by the presence of phytohaemagglutinin.

This work was supported in part by a research grant from the National Institute of Child Health and Human Development, National Institutes of Health, U.S. Public Health Service, and in part by a training grant from the National Institute of General Medical Sciences. We thank Mrs. Sally Upchurch and Dr. Ralph Schrohenloer for technical assistance and Miss Lois Barringer for assistance with the fluorescent microscopy.

## Identification of Host and Host Antibodies from Mosquito Blood Meals

INVESTIGATION of insect vectors of disease requires accurate information about their feeding habits and preferences. Mosquitoes, for example, serve as vectors for malaria, yellow fever, and the encephalitides. Each species or sub-species shows a varying degree of preference for man or other animals, and so it is most important to identify the host. Those Culicidae that do not favour man as host are not likely to be human disease vectors.

Different techniques have been employed to identify the source of blood meals, and some have met with a measure of success<sup>1,2</sup>. Even the best methods necessitate

the use of highly purified antisera for cross-reaction with diluted, extracted contents of mosquito stomach as antigen. We have recently worked out a method of micro-immunological analysis by means of a system based on a micromanipulator<sup>3</sup>. This report presents our findings so far on the identification of blood meals from *Culex* and *Anopheles* mosquitoes. Using micro-double diffusion in agar and micro-complement fixation tests on the blood from each mosquito stomach, we have successfully identified the host as well as the antibodies carried by the host, and within a general range have identified the antibody titre.

For double diffusion in agar, microtubes were prepared with short columns of 1 per cent agar. To make these microtubes, a length of borosilicate tubing (outer diameter 0.85 mm) was used to draw up a column of agar. A 10 mm microtube was cut off from this length of tubing to incorporate a 2.0 mm column of agar, which was positioned midway in the tube with a steel wire. A number of these agar-filled microtubes were mounted on a specially constructed carrier frame. The tests were then carried out using a microscope (magnification of  $\times 20-35$ ) and a micromanipulator. The details of preparation and filling of similarly sized microtubes for the micro-complement fixation tests are discussed elsewhere<sup>3</sup>.

Rabbits, dogs and humans were used as hosts. The rabbits and one of the dogs were sensitized to one of three antigens: bovine serum albumin, whole human serum, or Southern Bean mosaic virus (SBMV). *Culex pipiens* and *Anopheles quadrimaculatus* mosquitoes were trapped in isolated areas close to places of emergence to lessen the complication of previous blood meals, and were kept singly in small beakers covered with cheesecloth. They fed readily on the arm of human subjects or the ear of rabbits and dogs. After feeding, the mosquitoes were placed either in a refrigerator at 6°-9° C or at room temperature (25°-28° C) before experiments were run to define test stability under different conditions of time and temperature.

At periods ranging from 15 min to 12 days after a blood meal of approximately 1-2  $\mu$ l., each fed mosquito was killed on a glass slide and dissected. The blood meal in its peritrophic membrane was easily separated from the mid-gut region in all but the freshest samples. This unbroken sac was pulled up by light suction into a standard 1.3 mm microhaematocrit tube. The tube was sealed and centrifuged for 3-5 min on a standard microhaematocrit centrifuge. When the blood meal was old, the peritrophic membrane became rather hard and inelastic, containing clotted and lysed blood meal residue. Five to ten microlitres of 0.15 molar sodium chloride were added to the residue before centrifugation in these cases. Cross-reaction of a host sample with other than host-specific antiserum has been a great problem in other work on identification of blood meals<sup>4</sup>. This difficulty has not occurred in these microtests, but we do not know whether it is because of high test sensitivity or because more highly purified antisera are being used.

The micro-double diffusion test in agar takes only 2-4 h unless the blood meal samples are very old and have to be highly diluted; in the latter case, the test is left overnight. Five precipitin bands were present after 6 h in a test of whole human serum against 1:1 blood meal serum taken from a mosquito stomach. The mosquito took the blood

Table 1. MICRO-DOUBLE DIFFUSION IN AGAR ON MOSQUITO BLOOD MEALS

Fig. 2. The same mosquito blood meals as illustrated in Fig. 1, versus anti-rabbit goat serum (Pentex). This blood meal, like others, gave no precipitin reaction with either of the controls used, tobacco mosaic virus suspension and anti-human serum.

meal from a rabbit carrying a high antibody titre to human serum. No reaction was present with rat, duck, or dog serum. Photos show micro-double diffusion in agar (magnification,  $3.5 \times 6$ ) of host antibody reaction (Fig. 1), and host identification precipitin bands (Fig. 2).

Table 1 shows that *Culex* blood meals can be identified as to host and host antibodies after as long as 12 days if the mosquito is refrigerated. The *Anopheles* were quicker to digest blood meals, and no longer gave satisfactory tests after one week at  $1^\circ\text{C}$ , one day at  $28^\circ\text{C}$ .

In old blood meals (Table 1) the host antiserum can be identified several hours longer than the host can be identified. Perhaps this reflects the protein digestion pattern of the mosquito (the mosquito may digest globulin fractions containing antibody last). Preliminary results on human blood meals indicate that human serum albumen disappears quickly during digestion of blood meals.

## BIOCHEMISTRY

### Specificity of Cleavage of Chitotriose by Lysozyme

AFTER the recent determination of the structure of lysozyme in the crystalline state<sup>1</sup> we have become interested in chemical and kinetic approaches to the study of its mechanism of action in solution.

The region of the crystalline enzyme to which inhibitors such as *N*-acetyl-D-glucosamine and chitobiose bind has been identified by X-ray analysis methods<sup>2</sup>, and the smallest known substrate for lysozyme, chitotriose<sup>3</sup>, has been shown to bind to the same cleft on the enzyme surface<sup>4</sup>. We have investigated the binding of chitotriose to lysozyme in solution and have shown<sup>5</sup> (unpublished work) that association with the trisaccharide affects tryptophanyl and carboxyl groups on the enzyme surface, in agreement with the results obtained from X-ray analysis<sup>2,4</sup>.

As chitotriose serves as a substrate for lysozyme<sup>3,6</sup> it was interesting to determine whether the enzyme selectively or preferentially cleaves one of the two  $\beta$ -(1-4) linked glycosidic bonds in the trisaccharide. Recent studies by Rupley<sup>7</sup> have shown that cleavage of the glycosidic bond farthest from the reducing end of the trisaccharide is indicated by carrying out the reaction in water labelled with oxygen-18. Cleavage of both glycosidic bonds with approximately equal frequency was, however, suggested by following transfer of trimer cleavage products to *N*-acetyl-D-glucosamine labelled with carbon-14. For this purpose we synthesized chitotriose in which the acetyl group of the sugar residue at the reducing end of the molecule was specifically labelled with carbon-14 (sugar residue A in Fig. 1) by methods related to those used by Leaback and Walker<sup>8</sup> to obtain *N*-acetyl-D-glucosamine from 1,3,4,6-tetra-*O*-acetyl, D-glucosamine hydrochloride. Peracetylated chitotriose was obtained by the method of Zechmeister and Toth<sup>9</sup> and was converted to chloro, decaacetyl-chitotriose using acetic anhydride and dry hydrochloric acid. Treatment of this compound with nitromethane containing 0.1 per cent 0.1 normal hydrochloric acid resulted in the formation of decaacetyl-chitotriose, *N*<sup>1</sup>-monohydrochloride. Acetylation with acetic anhydride labelled with carbon-14 gave undecaacetyl-chitotriose-*N*<sup>1</sup> labelled with carbon-14 which on de-*O*-acetylation gave the labelled trisaccharide shown in Fig. 1.

Fig. 1. Structure of chitotriose with the acetyl group of the hexosamine ring at the reducing end of the trisaccharide labelled with carbon-14.

Incubation of this labelled trisaccharide ( $10^{-2}$  molar) at pH 5.0 (acetate,  $\mu = 0.1$ , containing 0.01 molar sodium chloride) at  $40^\circ\text{C}$  for 6 h followed by fractionation of the resulting oligosaccharide mixture by gel filtration resulted in the pattern shown in Fig. 2B. Paper chromatography<sup>10</sup> confirmed the identity of the materials in each chromatographic peak. From the decrease in chitotriose concentration it was estimated that 35 per cent of the trisaccharide had been degraded by the enzyme. It was evident that in addition to hydrolysis of chitotriose to yield chitobiose and *N*-acetyl-D-glucosamine transglycosylation had also occurred to yield some chitotetraose. The specific activities of the oligosaccharides compared with the original chitotriose (18,700 c.p.m./ $\mu\text{mole}$ ) were 12,600

c.p.m./ $\mu$ mole for chitobiose and 6,400 c.p.m./ $\mu$ mole for *N*-acetylglucosamine. Because of the low yield of tetrasaccharide obtained it was not possible to estimate its specific activity with confidence. The results show that neither of the two glycosidic bonds are split with complete selectivity by the enzyme but that preferential cleavage of the bond farthest from the reducing end of the trisaccharide occurs.

Estimation of the relative amounts of chitobiose and *N*-acetyl-D-glucosamine produced revealed that the disaccharide was in excess of the monosaccharide by a factor of approximately 2:1 on a molar basis. This result, coupled with the observed formation of tetrasaccharide, is consistent with a major pathway for cleavage of the trisaccharide depicted schematically in Fig. 3. According to this scheme an enzyme-substrate complex is first formed, which then gives rise to a complex of free disaccharide and enzyme-monomer. The enzyme-monomer complex can react either with water to yield free enzyme and free monosaccharide or with trisaccharide to yield free enzyme and tetrasaccharide. Cleavage of the glycosidic bond nearest the reducing end of the trisaccharide substrate could, by a similar scheme, result in formation of chitopentaose. We have not observed any

of this oligosaccharide, but this does not exclude its formation, as the relative rates of cleavage of chitotriose, chitotetraose and chitopentaose have been shown to be 1:7:300 (ref. 11).

At present it is not possible to decide whether the substrate or products are at any stage of the reaction covalently attached to the enzyme. Further experiments to elucidate the mechanism of action of lysozyme are in progress.

The black circles show the *N*-acetylhexosamine rings in which the *N*-acetyl group is labelled with carbon-14. Solid lines represent covalent bonds while dotted lines depict other types of interaction.

### Succinylated Meromyosins

It has been found that on succinylation myosin releases a component of low molecular weight that can be isolated by fractionation with sulphate<sup>1</sup>. We now wish to report that this component is located in the heavy meromyosin part of the myosin molecule.

Myosin was prepared from rabbit skeletal muscle by extracting the mince for 15 min in a cold room with three volumes of a solution containing 0.3 molar potassium chloride, 0.15 molar phosphate buffer, pH 6.6, and 0.5 mmolar ATP. The suspension was diluted with an equal volume of cold distilled water and was centrifuged; the myosin in the supernatant was precipitated by dilution with 6.5 volumes of distilled water at 0° C. Any remaining *F*-actin was removed from the myosin according to the procedure of Portzehl, Schramm and Weber<sup>2</sup>; the myosin preparation so obtained was reprecipitated twice and dissolved in 0.5 molar potassium chloride, 0.05 molar phosphate buffer, pH 6.2.

Heavy meromyosin was prepared from this myosin by digestion with trypsin, at pH 6.2, for 5 min at 25° C. The weight ratio of myosin to trypsin was 200:1, and the reaction was stopped with trypsin inhibitor, twice the weight of the trypsin. The reaction mixture was dialysed against 7 mmolar phosphate buffer, pH 7.0, to precipitate the light meromyosin and undigested myosin. The heavy meromyosin was isolated from the supernatant after centrifugation at high speed. Light meromyosin fraction 1 was prepared from the precipitate according to the method of A. G. Szent-Györgyi, Cohen and Philpott<sup>3</sup>.

To prepare light meromyosin, myosin was digested for 40 min at 25° C, pH 6.2, with trypsin at a weight ratio of 100:1. The digestion mixture was dialysed against 7 mmolar phosphate buffer, pH 7.0; the light meromyosin precipitate was purified by twofold reprecipitation and dissolved in 0.5 molar potassium chloride and 0.05 molar phosphate buffer, pH 7.0.

The meromyosins were succinylated with 1.4 mg of succinic anhydride per mg of protein at room temperature while the pH was kept constant at 7.0 by addition of base. The reaction mixtures were afterwards dialysed against large volumes of a solution containing 0.5 molar potassium chloride, 0.05 molar phosphate buffer, pH 7.0.

Fig. 1 shows the ultracentrifugal patterns of light meromyosin and succinylated light meromyosin, at a protein concentration of 5 mg/ml. Both the original and the modified light meromyosin sediment as a single peak for as long as 4 h with a sedimentation coefficient of 2.2 *S*. Similar results were obtained when light meromyosin fraction 1 and succinylated light meromyosin fraction 1 were compared; the sedimentation behaviour of both was identical. Furthermore, determinations of molecular weight with light scattering showed no difference between the untreated and the succinylated light meromyosin fraction 1, and gave a value of 160,000–170,000 for both.

In contrast to light meromyosin, the gross structure of which is unchanged by succinylation, heavy meromyosin is split into two components. This phenomenon is demonstrated in the upper row of Fig. 2, which shows the ultracentrifuge pictures of heavy meromyosin and succinylated heavy meromyosin. Whereas heavy meromyosin is homogeneous (sedimentation coefficient, 5.6 *S*), succinylated heavy meromyosin gives two peaks (sedimentation coefficients, 6.4 *S* and 1.3 *S*, respectively). We were able to isolate the two fractions from the succinylated heavy meromyosin with the aid of ammonium sulphate. Fraction 1 was precipitated in a cold room from the mixture at 55 per cent saturation, washed with 55 per cent ammonium sulphate, then dissolved, and dialysed against a solution containing 0.5 molar potassium chloride and 0.05 molar phosphate, pH 7.0. To obtain fraction 2, the supernatant, obtained from the mixture at 55 per cent ammonium sulphate saturation, was dialysed against distilled water to remove salts and then freeze-dried; it was then dissolved and dialysed against 0.5 molar potassium chloride and 0.05 molar phosphate, pH 7.0.

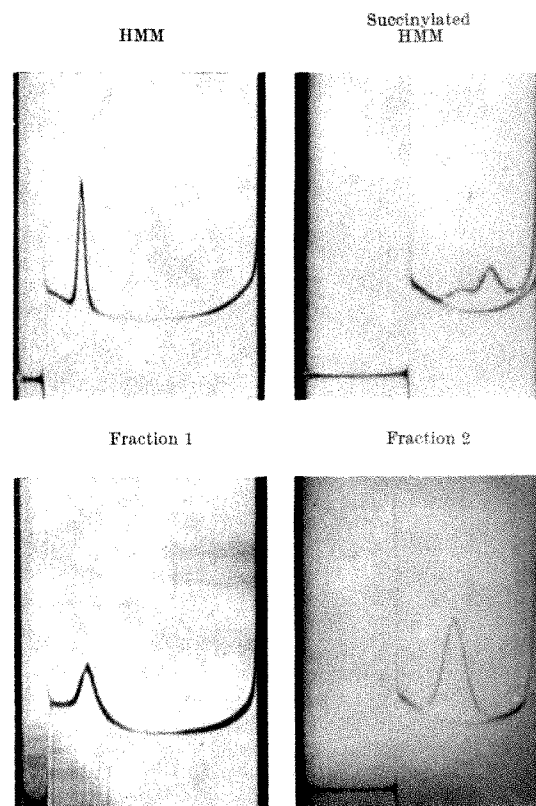

Fig. 2. Ultracentrifugal patterns of heavy meromyosin (HMM), succinylated heavy meromyosin, fraction 1 and fraction 2 isolated from succinylated heavy meromyosin. Protein concentration, 3.3 mg/ml.; speed, 59,780 r.p.m.; temperature, 20.0° C; pictures taken after 24 min. Sedimentation proceeds from left to right.

The sedimentation patterns of the isolated fractions 1 and 2 from the succinylated heavy meromyosin are shown in the lower row of Fig. 2. Both these fractions sediment as a single peak with a sedimentation coefficient of 6.2 *S* and 1.3 *S*, respectively.

These data indicate that succinylation produces no detectable alteration of the light meromyosin, while under identical conditions the heavy meromyosin is split into two components. We therefore conclude that the component of low molecular weight released on succinylation of myosin originates solely from the heavy meromyosin part of the myosin molecule.

### Relative Distribution of Enzymes and Prosthetic Groups

THE *Enzyme Classification*<sup>1</sup>, published in 1961, is a convenient source of authoritative data on the numbers and types of enzymes. The recently revised version of the list<sup>2</sup> has extended the available data and made possible an assessment of the changes produced by 5 years of increasingly fruitful work in the field of enzymology. The figures quoted in this communication are based on my own examination of the two editions of the *Enzyme*

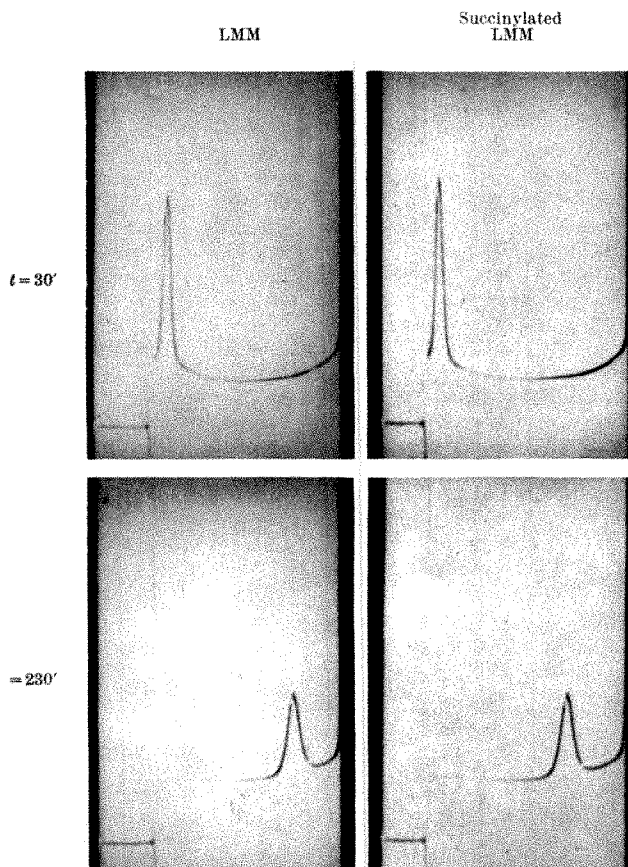

Fig. 1. Ultracentrifugal patterns of light meromyosin (LMM) and succinylated light meromyosin. Protein concentration, 5 mg/ml.; speed, 59,780 r.p.m.; temperature, 20.0° C.

**Classification.** In spite of any numerical errors which may have resulted, I think that the findings are quite clear and of general interest.

In the first place, the total number of enzymes recognized in the classification has risen from 703 in 1961 to 884 in 1965, an average of about 40 per year. The alterations within the six principal enzyme groups as a result of this substantial increase are shown in Table 1, which records the total number of enzymes in each group and the corresponding percentage of the total which each represents. It is quite clear that there is virtually no change in the relative proportions. Bearing in mind that each "enzyme" in the list is generally represented in several different forms of living organism, and that recent work has begun increasingly to embrace such comparative studies, it seems reasonable to presume that the figures in Table 1 are a close approximation to the overall distribution of enzyme types in living organisms generally.

The distribution of prosthetic groups can also be obtained from the classification, and is analysed in Table 2. The prosthetic groups indicated there represent all the groups now recognized as being able to form an integral and reactive portion of enzyme structure. The recent report of a previously unknown type of prosthetic group, possibly a quinone<sup>3</sup>, indicates that further additions to the table are in prospect. Some further provisos must be noted: (i) for the purposes of Table 2 I have not distinguished between cofactors and prosthetic groups, because in general it appears reasonably certain that in both cases the molecule is involved directly in the catalytic reaction; (ii) as an exception to the previous statement I have not felt justified in including enzymes which require metals except when the metal is definitely known to be firmly bound to the protein; as a result, the distribution of "metal enzymes" is certainly higher than shown here—how much higher can only be surmised until more evidence on reaction mechanisms is available; (iii) in a few cases where two distinct and different prosthetic groups occur in the same enzyme I have counted two enzymes for the purposes of Table 2.

Table 2 shows clearly that the total number of enzymes which have such auxiliary groups (at least 16 per cent of the total) is greater than the remarks of the Enzyme Commission (ref. 1, page 29; ref. 2, page 26) would lead one to imagine, but it is nevertheless equally clear that the great majority of enzymes carry out their catalytic activity in virtue of their constituent amino-acids alone. Pyridoxal phosphate is the commonest auxiliary group, both numerically and in its wide distribution.

The distribution of these groups is not now so sharply restricted within the principal groups of enzymes as was the case in the 1961 classification. One is tempted to make a comparison with the zoological classification and to suppose that the apparently aberrant enzymes which are now appearing in the classification are in some sense "missing

links" between the principal enzyme groups. It is also striking that a more detailed consideration of the enzyme sub-groups shows that auxiliary groups are very often even more restricted than Table 2 implies. This is more difficult to detail at present because information on reaction mechanisms becomes more important at this level. Also, one does not know to what extent the present classification will be revised as further knowledge accumulates. Obvious examples, however, are the transferases of sub-group 2.6.1.x, mainly catalysing amino-acid reactions, in which sixteen out of the twenty are pyridoxal phosphate enzymes (out of eighteen such enzymes in the group as a whole); and the ligases of sub-group 6.4.1.x, catalysing the formation of carbon-carbon bonds, where all four enzymes contain biotin (out of five such enzymes in the whole classification). One can also note that Group I enzymes contain all but one of the known flavin enzymes, and that all but two of these are in sub-groups 1 to 10. Within sub-groups 1 to 10, however, there is at present a clear distinction between enzymes requiring NAD or NADP and the rest. None of the former contain flavin, whereas the latter may (along with various other prosthetic groups, or none at all). One may say that all the dehydrogenases classed in sub-groups 1.(1-10).1.x use NAD or NADP exclusively as acceptor cofactor and do not contain flavin, whereas dehydrogenases in the remainder of this section [1.(1-10).(2-99).x] do not use NAD or NADP, but may contain flavin. These and other relationships of the Group I enzymes are very conveniently brought out by plotting a table with sub-groups reading down the page against the type of acceptor reading across. This gives a series of columns showing the acceptor with which the various enzymes react. In such a table the enzymes requiring NAD or NADP comprise all the entries in the first column. Other characteristics, such as the type of prosthetic group, are readily displayed in the table. Unfortunately, this treatment is not applicable to any of the other enzyme groups.

The results of general considerations as presented earlier, and of more detailed examinations as in the matrix just mentioned, suggest possible relationships between enzymes and enzyme groups which are not immediately apparent in the printed version. For example, contrary to what was stated previously, Katzen and Buchanan<sup>4</sup> have recently reported that methylene tetrahydrofolate reductase, 1.5.1.5, is an enzyme containing FAD. On the other hand, they also found that it did not require either NAD or NADP. On both grounds, therefore, it seems probable that either these authors were not studying enzyme 1.5.1.5 or else that enzyme 1.5.1.5 has been incorrectly classified. The ability to point out discrepancies such as this strengthens confidence both in the type of analysis given here and in the classification on which it is based. It appears that in an encouragingly high proportion of cases the classification based on overall reaction is turning out to be the same as that which would be based on the true reaction mechanism. One may hope to recognize further similarities based on the reaction mechanism, some of which are already emerging, as, for example, the lysine and serine enzymes.

### Inhibition of Alcohol Dehydrogenase by Chloroquine

CHLOROQUINE is an anti-malarial drug which is also used in the treatment of rheumatoid arthritis. It has been shown to inhibit various thiol-containing enzymes such

as succinic dehydrogenase<sup>1</sup>, glutamic dehydrogenase<sup>2</sup> and the  $\alpha$ -ketoglutarate oxidizing system<sup>3</sup>. The prolonged administration of large doses of chloroquine causes the development of an irreversible retinopathy<sup>4</sup>. Chloroquine accumulates in the retinal pigment epithelium<sup>5</sup> and it also inhibits NADH-monodehydroascorbic acid transhydrogenase, a thiol-containing enzyme present in retinal microsomes<sup>6</sup>. Alcohol dehydrogenase is an important enzyme in the visual cycle, being involved in the retinol-retinal conversion, and in this communication it has been established that this thiol-containing enzyme is competitively inhibited by chloroquine.

Yeast alcohol dehydrogenase was obtained from Boehringer G.m.b.H., and the stock suspension (30 mg/ml.) was diluted 500-fold with water before use. The enzyme was assayed at 37° C by measuring the rate of oxidation of NADH at 368 m $\mu$  in a Unicam 'SP 700' recording spectrophotometer. Chloroquine absorbs strongly at 340 m $\mu$ , the wavelength at which NADH is usually measured, but at 368 m $\mu$  it has zero absorption while NADH still has 50 per cent of its maximum absorption.

The assay mixture contained 0.1 ml. of enzyme suspension, ethanol (0.36 molar), NADH and phosphate buffer, pH 8.0, up to a final volume of 3 ml. The final concentration of NADH varied from 0.034 mmolar to 0.35 mmolar and that of chloroquine from 1  $\mu$ molar to 1 mmolar. The reaction was started by the addition of the enzyme. NADH was omitted from the blank cell.

2,3-Dimercaptopropanol (BAL) reverses the inhibitory effect of chloroquine on the  $\alpha$ -ketoglutarate oxidizing system<sup>3</sup>. The protective effect of BAL on the chloroquine inhibition of alcohol dehydrogenase could not be investigated, because BAL, at a final concentration of 2 mmolar, itself caused inhibition by reaction with the zinc moiety of the alcohol dehydrogenase. Reduced glutathione was found not to inhibit alcohol dehydrogenase and reversal of chloroquine inhibition was attempted with this compound. The reduced glutathione (2 mmolar, final concentration) was added to the reaction mixture before the addition of 1 mmolar chloroquine; the NADH concentration was 0.25 mmolar.

Chloroquine inhibited alcohol dehydrogenase at all concentrations of NADH used (see Table 1); the maximum inhibition observed was at chloroquine and NADH concentrations of 1 mmolar and 0.034 mmolar, respectively. The inhibitory effect became less pronounced with decrease in chloroquine concentration or increase in NADH concentration. Chloroquine, at a final concentration of 1  $\mu$ molar, did not exert any inhibition on the reaction.

The results obtained with chloroquine at a fixed concentration of 1 mmolar and varying NADH concentrations were plotted according to the method of Lineweaver and Burke; the reciprocal of the velocity of the reaction (change in extinction at 368 m $\mu$ /min) was plotted against the reciprocal of the NADH concentration (Fig. 1). The plot obtained was characteristic of that given by competitive inhibitors, and both lines crossed the vertical axis at the same point. In the presence of glutathione (2 mmolar, final concentration) the inhibitory effect of 1 mmolar chloroquine was unaltered.

These results demonstrate that alcohol dehydrogenase, in common with several other thiol-containing enzymes, is inhibited by chloroquine, and the inhibition is of a competitive type, as is that of glutamic dehydrogenase<sup>2</sup>.

Histopathological investigations of chloroquine retinopathy have shown that it has some features in common

Fig. 1. Inhibition of alcohol dehydrogenase by chloroquine: data plotted according to the method of Lineweaver and Burke.  $1/v$  is the reciprocal of the velocity of the reaction (change in extinction at 368 m $\mu$ /min) and  $1/[S]$  is the reciprocal of the NADH concentration. ○, No chloroquine; ●, plus 1 mmolar chloroquine.

with that caused by iodoacetate<sup>7</sup>, another inhibitor of thiol-containing enzymes, and it is probably through an effect on enzyme thiol groups that chloroquine produces a retinopathy.

### Enzyme Hydrolysis of 6-Benzylamino-9B D-Ribofuranosylpurine and 6-Hexylamino-9B D-Ribofuranosylpurine

THE N-6 substituted adenines with a lipophilic radical show a biological activity of the kinetin type<sup>1,2</sup>. The ribosides of substituted adenine present an activity at least identical to that of the free bases<sup>2,3</sup>; this could be possibly attributed to their hydrolysis and the subsequent formation of the free bases. To test this hypothesis, the action of nucleoside phosphorylase from *Escherichia coli* was analysed on the ribosides of two kinins: 6-benzylaminopurine and 6-hexylaminopurine. The method used for the enzyme preparation was that of Paegle and Schlenk<sup>4</sup>; the fraction of protein precipitated with ammonium sulphate between 60 and 80 per cent of saturation was retained and then dialysed. Preliminary tests on the hydrolysis of nucleosides were effected with inosine and adenosine.

The kinetics of the reaction were followed either spectrophotometrically<sup>5</sup> or by separating the ribosides from the liberated bases resulting from the hydrolysis, with thin-layer (cellulose) chromatography. For the spectrophotometrical analysis the reaction mixture was 0.2  $\mu$ moles of nucleoside; 0.2 ml. of catalase solution (2 mg/

Table 1. INHIBITION OF ALCOHOL DEHYDROGENASE BY CHLOROQUINE AT TWO CONCENTRATIONS OF NADH

ml.); 0.5 ml. of xanthine-oxidase solution (0.04 mg/ml.) for inosine hydrolysis or 0.2 ml. of this solution (2 mg/ml.) for adenine and substituted adenine nucleosides; 0.02 ml. of bacterial extract. The total volume was adjusted to 4 ml. with a phosphate buffer pH 8 and 0.03 molar.

For the chromatographic analysis the reaction mixture was 0.5  $\mu$ moles of nucleoside; 0.05 ml. or 0.1 ml. of bacterial extract. The total volume was adjusted to 1 ml. with the same buffer.

Table 1. SPECTROPHOTOMETRICAL DETERMINATION OF ENZYME HYDROLYSIS OF VARIOUS PURINE RIBOSIDES BY NUCLEOSIDE PHOSPHORYLASE

	Inosine $\Delta$ O.D. (290 $\mu$ )	Adenosine $\Delta$ O.D. (305 $\mu$ )	6-Benzyl- aminopurine $\Delta$ O.D. (305 $\mu$ )	6-Hexyl- aminopurine $\Delta$ O.D. (305 $\mu$ )
A	0.41	0.24	0.17	0.45
B	0.01	0.00	0.00	0.01
C	0.00	0.00	0.00	0.00
D	0.01	0.00	0.00	0.00
E	0.56	0.12	0.10	1.11

In Table 1 are shown variations of the optical density (in the wavelength corresponding to the maximum absorption of the oxidated bases) after 48 min of hydrolysis for different reaction mixtures. A—complete reaction mixture; B—without nucleosides; C—without xanthine oxidase; D—without nucleoside phosphorylase; E—nucleosides replaced by the free bases.

It is clear that the oxidation of nucleosides by xanthine oxidase is negligible compared with the oxidation of the free bases (D and E). With nucleoside phosphorylase, the situation is reversed, that is, the four ribosides (and especially the ribosides of 6-benzylaminopurine and 6-hexylaminopurine) are hydrolysed, and the liberated bases are then oxidated by xanthine oxidase (A). The presence of nucleosides (B), nucleoside phosphorylase (D) and xanthine oxidase (C) is necessary to make the reaction possible.

The separation of the free bases from the non-hydrolysed ribosides was possible by thin-layer chromatography of an aliquot fraction of hydrolysis products using distilled water as a solvent. In Fig. 1 it can be seen that the bases hypoxanthine and 6-benzylaminopurine effectively appeared during hydrolysis of their corresponding ribosides.

Consequently, nucleoside phosphorylase from *E. coli* is able to hydrolyse ribosides of the N-6 substituted adenine 6-benzyl- and 6-hexylaminopurine which present a kinetin activity.

## Effect of Growth Hormone on the Isolated Pancreatic Islets of Rat *in vitro*

ISLETS of Langerhans were isolated by the technique of Kostianovsky and Lacy<sup>1</sup> from the pancreases of intact rats, as well as from rats hypophysectomized 4 weeks previously, some of which were treated for the last 3 days with 2 mg bovine growth hormone/day. Following an equilibration period of 20 min in cold Krebs-Ringer bicarbonate buffer, pH 7.2, with 0.6 mg/ml. glucose, five or six islets were placed in each incubation flask with 0.5 ml. of the same buffer, and incubated at 37° C with continuous gassing, using a mixture of 95 per cent oxygen and 5 per cent carbon dioxide. After incubation for 15 min, the islets were transferred to a second incubation medium with either 0.6 or 3.0 mg/ml. glucose plus tritiated D,L-leucine (0.01 mc.,  $1.27 \times 10^{-5}$  mmolar) and incubated for a further period of 15 min. At the end of the incubation, the islets were removed, washed with cold buffer containing 1 mg/ml. unlabelled D,L-leucine, and homogenized with 0.5 ml. of 10 per cent trichloroacetic acid in a tissue micro homogenizer. Insulin extraction from the islets homogenized with TCA was carried out according to the procedure described by Taylor<sup>2</sup>. Portions of the acid-alcohol extract were used for insulin determination and for counting the incorporation of tritium in the insulin-anti-insulin precipitate. The precipitate that remained after extraction with acid-alcohol was treated with chloroform-methanol-ether in order to remove the fat, and the protein content was determined by the micro-method of Lowry<sup>3</sup>. Release of insulin into the incubation media, and the insulin content in the extracted islets, were determined by the immunoassay method of Herbert<sup>4</sup>, in which the separation of free insulin and insulin bound to antibody is achieved by "instant dialysis" with 'Dextran 80' coated charcoal. Some twenty islets from each animal were studied; two sets were incubated with 0.6 mg/ml. glucose in the two cycles (baseline), while another two were submitted to glucose stimulation (3.0 mg/ml.) in the second cycle.

The results are summarized in Table 1. In all cases the amounts of insulin are expressed in relation to protein content.

The present results show that a high concentration of glucose significantly stimulates release of insulin and incorporation of tritiated leucine by the isolated islets from normal rats. The increased incorporation of leucine, as an indication of increased insulin synthesis, may help to explain the finding of an unchanged insulin content of the stimulated islets by indicating that synthesis and release may have been equally enhanced.

Islets from the hypophysectomized rats had a significantly reduced insulin content, a lower insulin output, and a diminished insulin synthesis compared with the normal animals, either at a low or a high glucose concentration. Furthermore, the glucose concentration of 3.0 mg/ml. failed to stimulate the release or synthesis of insulin to values higher than basal.

Treatment for 3 days with bovine growth hormone corrected most of those parameters. The islets again responded to stimulation with glucose. The release, content and synthesis of insulin were all significantly higher than in islets from hypophysectomized untreated rats, and did not differ from the same factors in normal islets stimulated by glucose.

The present *in vitro* procedure has the advantage that it is possible to study islets directly in a pure preparation. In the particular case of the action of growth hormone on islets, the method eliminates the effect of the hormone on acinar tissue, a problem that has handicapped most of previous preparations of pancreas *in vitro*. The incorporation of labelled amino-acids into the insulin fraction, as an indication of its synthesis, is more meaningful, as the possibility of contamination by other non-islet proteins is reduced.

Table 1. INCUBATION OF ISOLATED ISLETS OF LANGERHANS OF RATS

	Insulin release ( $\mu$ U insulin/ $\mu$ g protein)		Islets insulin content ( $\mu$ U insulin/ $\mu$ g protein)		Tritiated leucine incorporation (c.p.m./mU insulin)	
	Baseline	Stimulation	Baseline	Stimulation	Baseline	Stimulation
Normal (18)	18.40 $\pm$ 3.81†	46.70 $\pm$ 15.05*	4,778 $\pm$ 873.11	3,978 $\pm$ 435.22	4.30 $\pm$ 0.81	11.57 $\pm$ 2.10*
Hypophysectomized (14)	6.80 $\pm$ 2.50	16.32 $\pm$ 5.48	1,714 $\pm$ 388.25	2,071 $\pm$ 405.30	5.98 $\pm$ 1.81	6.64 $\pm$ 1.81
Hypophysectomized + bovine growth hormone (8)	10.51 $\pm$ 2.86	29.00 $\pm$ 0.71*	1,400 $\pm$ 234.50	3,700 $\pm$ 822.50*	8.86 $\pm$ 1.78	15.63 $\pm$ 2.34*

\* The difference between response to glucose stimulation and baseline is significant ( $P < 0.05$ ). Number of experiments in parentheses.

† Mean  $\pm$  standard error of the mean.

The results reported here indicate that growth hormone increases the rate of synthesis and of release of insulin by the islets. These effects are more evident when they are stimulated by a high concentration of glucose, which suggests that the hormone may act by enhancing the activating mechanism of this sugar on beta cells.

### C-Terminal Sequence of Pig Growth Hormone

THE wide interest in the comparative biochemistry of pituitary growth hormone prompted this investigation of the nature of the C-terminal region of pig growth hormone. Recent reports on the C-terminal octapeptide of ox growth hormone<sup>1,2</sup>, and on the entire amino-acid sequence of human growth hormone<sup>3</sup>, provide an interesting basis for comparison.

The purified pig growth hormone used in this work was kindly provided by Professor A. E. Wilhelmi. It had a biological potency of 2.3 IU/mg. Before digestion with carboxypeptidase, the hormone was reduced with  $\beta$ -mercaptoethanol in 8 molar urea<sup>4</sup>, and the sulphhydryl groups formed were reacted with iodoacetamide. This preparation of reduced and carbamidomethylated (RCAM) protein was dissolved in 0.1 per cent sodium bicarbonate containing 1 per cent sodium dodecyl sulphate at a protein concentration of 1 per cent. Carboxypeptidase A (Sigma, DFP treated) was added to make an enzyme: substrate ratio of 1:100. The mixture was incubated at room temperature, and aliquots were removed at 15 min, 1 h and 20 h. The liberated amino-acids were analysed by paper electrophoresis<sup>5</sup>. The results (Fig. 1) indicate that phenylalanine is C-terminal, followed by alanine and half-cystine. These results are calculated from an assumed molecular weight of 22,000 (refs. 6-8).

The procedure used by Wallis<sup>1</sup> to isolate the C-terminal peptide of ox growth hormone was followed exactly to isolate the corresponding peptide of pig growth hormone. Thus, a tryptic digest of the performic oxidized hormone was run on paper electrophoresis at pH 2.1, and the peptide which hardly moved from the origin toward the cathode was purified by electrophoresis at pH 6.5. The amino-acid composition of this peptide, determined on a Technicon 'AutoAnalyzer', was Phe (1.8), Ser (1.9), Glu (1.0), Ala (1.2), Val (0.9), CySO<sub>3</sub>H (0.9). Treatment of the peptide with carboxypeptidase showed that phenylalanine is C-terminal, and Edman-Dansyl degradation<sup>9</sup> revealed the N-terminal sequence Phe-Val-Glu-. Diges-

tion of the peptide with pronase released free phenylalanine and valine, and two tripeptides, Pr<sub>1</sub> [Glu (1.0), Ser (1.8)] and Pr<sub>2</sub> [(CySO<sub>3</sub>H (1.1), Ala (1.0), Phe (1.0)]. Analysis by the dansyl method<sup>10</sup> showed glutamic acid to be the N-terminal residue of Pr<sub>1</sub>, and cysteic acid of Pr<sub>2</sub>. These data are sufficient to deduce the structure shown in Fig. 2a.

Fig. 1. Amino-acids released from reduced and carbamidomethylated pig growth hormone (RCAM-PGH) by carboxypeptidase A. The abbreviation CySCAM refers to S-carbamidomethylcysteine, which represents half-cystine in the native hormone.

Fig. 2. The C-terminal amino-acid sequences of (a) pig growth hormone; (b) ox growth hormone<sup>1</sup>, and (c) human growth hormone<sup>3</sup>.

The sequence reported here is rather different from the sequence, -(Ser, Leu)-Phe-Ala-Phe, reported earlier<sup>11</sup>, but a comparison with the C-terminal sequences of ox growth hormone<sup>1</sup> (Fig. 2b) and human growth hormone<sup>3</sup> (Fig. 2c) shows several points of similarity. These results, together with recent investigations of the molecular weights<sup>6-8</sup> and immunological properties<sup>12</sup> of several species of growth hormone, indicate that the growth hormone molecules of various species could be much more similar than was earlier believed.

It is of interest to note that the amino-acid substitutions in the structures in Fig. 2 all involve single base changes in the genetic code<sup>13</sup>. The theory<sup>14</sup> that this is a requirement for amino-acid substitution, however, does not necessarily apply in this comparison of several species, since it was devised to explain point mutations within a given species.

I thank Drs. A. Stockell Hartree, H. B. F. Dixon and R. N. Perham for their help and encouragement, and Dr. M. Wallis for communication of his results before publication. This work was carried out during the tenure of

a postdoctoral fellowship granted by the U.S. National Science Foundation.

### Effect of Various Hormones on the<sup>3</sup>Milk Ejection Response of Tissue isolated from the Rat Mammary Gland

A SENSITIVE *in vitro* bioassay for oxytocin has been developed which makes use of the milk-ejection response of tissue from the mammary gland of lactating rats<sup>1</sup>. The object of the present experiments was to determine the specificity of this assay. The specificity of the response of mammary gland tissue to oxytocin, *in vitro*, has been a matter of controversy ever since Mendez-Bauer *et al.*<sup>2</sup> used the response of this tissue as a quantitative assay for oxytocin. These workers reported that the contractions of rabbit mammary strips were highly specific for oxytocin. Subsequently other investigators found that mammary strips from lactating rats contracted in response to a variety of substances, for example, arginine-vasopressin<sup>3,4</sup>, acetylcholine, epinephrine, norepinephrine, histamine and 5-hydroxytryptamine<sup>4</sup>. Mammary strips from lactating rabbits contracted when exposed to arginine-vasopressin and to acetylcholine<sup>5</sup>.

Mammary tissue contains two types of contractile cells, smooth muscle and myoepithelium<sup>6,7</sup>. There is no direct experimental evidence to indicate which of the two elements is responsible for milk ejection and which is concerned with the contractions of a strip of mammary tissue. It is conceivable that both the myoepithelial and smooth muscle cells participate in the contractions, while the myoepithelial cells are solely responsible for milk ejection. Conclusions concerning the oxytocin specificity of mammary gland tissue based on the contractions of strips may not therefore be relevant for the milk ejection response.

In the present experiments, milk ejection was measured by the technique of Van Dongen and Hays<sup>1</sup>. The time was determined between the application of the test substance to a small piece of mammary gland tissue and the ejection of milk. This interval, the latency, is quantitatively related to the concentration of the test substance. The following compounds were tested: syntocinon, bradykinin, 8-lysine-vasopressin, 8-arginine-vasopressin, pitocin, pitressin, adrenaline chloride, *l*-norepinephrine bitartrate monohydrate, histamine diphosphate, serotonin creatine sulphate, and acetylcholine chloride.

Lactating, primiparous, white rats with eight or more young and between the fifteenth and seventeenth days of lactation were used. The young were removed from the mother 5–8 h before the start of the experiment. The mother was anaesthetized with sodium pentobarbital (26 mg/kg body weight) and a portion of the fourth mammary gland was excised. Pieces approximately 2 mm<sup>3</sup>

were cut from the gland and stored in tissue culture medium containing 116.43 mmolar sodium chloride, 5.36 mmolar potassium chloride, 9.06 mmolar sodium dihydrogen phosphate, 0.81 mmolar magnesium sulphate, 1.80 mmolar calcium chloride, 27.74 mmolar sodium bicarbonate, and 5.55 mmolar glucose. Horse serum was added to this solution (10 per cent final concentration). The pH was adjusted to 7.4 with 0.1 normal hydrochloric acid.

A total of six experiments was carried out. All the compounds were tested in every experiment, the sequence of testing being rotated from one experiment to another. The latencies were measured and analysed according to established statistical procedures<sup>8</sup>. In order to check all compounds in every experiment, it was necessary for the tissue sensitivity to remain constant for at least 4 h, and for spontaneous contractions to be minimal. For these reasons the experiments were done at 5° C.

Fig. 1. Relationship between hormone concentration and the time from exposure of the mammary tissue to hormone until the ejection of milk (latency). Isolated segments of rat mammary gland, 5° C. Results from six experiments. Each point represents mean of sixty determinations (over the range of concentrations  $4.4 \times 10^{-7}$  to  $4.4 \times 10^{-10}$  moles/l.); and ten to sixty determinations (between  $4.4 \times 10^{-10}$  and  $8.8 \times 10^{-12}$  moles/l.). ●, Syntocinon; ○, pitocin; ◆, pitressin; ▲, 8-lysine-vasopressin; △, 8-arginine-vasopressin; ■, acetylcholine.

Bradykinin, adrenaline chloride, *l*-norepinephrine bitartrate monohydrate, histamine diphosphate and serotonin creatine sulphate, at concentrations ranging from  $4.4 \times 10^{-7}$  to  $4.4 \times 10^{-12}$  moles/l., did not cause any ejection of milk. Syntocinon, pitocin, pitressin, 8-lysine vasopressin, 8-arginine vasopressin, and acetylcholine chloride, at concentrations ranging from  $4.4 \times 10^{-7}$  to  $8.8 \times 10^{-12}$  moles/l., did produce ejection of milk. Fig. 1 shows dose-response curves for these compounds. Each point on every curve (in the range of concentrations from  $4.4 \times 10^{-7}$  to  $4.4 \times 10^{-10}$  moles/l.) is the mean of sixty latencies. Below  $4.4 \times 10^{-10}$  moles/l. the milk ejection ability of all compounds became erratic, and it was not possible to obtain equal numbers of latencies for every compound. From  $4.4 \times 10^{-10}$  to  $8.8 \times 10^{-12}$  moles/l. each point on the curves is a mean of between sixty and ten latencies.

There were no significant differences among the dose-response curves for the various polypeptides. The results

from an analysis of variance on these data appear in Table 1. The results from an analysis of variance on the data from polypeptides and acetylcholine are given in Table 2. The dose-response curve for acetylcholine differed significantly from those for the polypeptides (compare Tables 1 and 2).

Under the conditions of our experiments, rat mammary tissue *in vitro* is stimulated by other neurohypophyseal hormones in addition to oxytocin and by acetylcholine, and hence is not specific for oxytocin. The discrepancy between our results and those of Rydén and Sjöholm, who found that adrenaline, noradrenaline, histamine and 5-hydroxytryptamine caused contractions of mammary gland strips at 38° C, may be explained by the fact that our experiments were carried out at 5° C. At this temperature the myoepithelial cells may be insensitive to these hormones. The *in vivo* bioassay, using the milk ejection response in lactating guinea-pigs as studied by Folley and Knaggs<sup>5</sup>, is highly specific for oxytocin; arginine or lysine vasopressin being only about one fifth as effective as oxytocin and acetylcholine several hundred times less effective. In terms of specificity therefore the *in vivo* assay seems to be the preferable method.

This work was supported by a grant from the U.S. Public Health Service.

## On the Site of Action of Luteinizing Hormone

THE site of action of luteinizing hormone in stimulating synthesis and secretion of ovarian steroid hormones has been the subject of some controversy. Armstrong *et al.*<sup>1,2</sup> have concluded that the primary action of this gonadotropin in rat lutein and rabbit ovarian interstitial cells is to facilitate conversion of stored cholesterol to progesterone, and suggested that increased incorporation of <sup>14</sup>C-acetate into steroids, when it occurs, is a consequence rather than a cause of this stimulation. Savard *et al.*<sup>3</sup> have proposed that LH increases steroidogenesis at least in part by a primary stimulation of the rate of *de novo* synthesis of sterols and steroids from small molecular precursors. In the experiments reported here, resolution of this controversy has been achieved for the rabbit ovarian interstitial gland by preventing cholesterol biosynthesis with *trans*-1,4-bis (2-chlorobenzyl-aminomethyl) cyclohexane dihydrochloride (AY9944), a compound which inhibits 7 dehydrocholesterol  $\Delta^7$ -reductase<sup>4</sup>.

Slices of ovarian interstitial tissue from mature New Zealand rabbits have been incubated in Krebs-Ringer bicarbonate buffer in the presence or absence of AY9944 (1 or  $2 \times 10^{-6}$  molar), and without or with luteinizing hormone (NIH-LH-B3, 1  $\mu$ g/ml.) in the incubation media. Net *in vitro* synthesis of progesterone and 20 $\alpha$ -hydroxy-pregn-4-en-3-one has been determined as previously described<sup>1</sup>, the mass being measured on the basis of the ability of these steroids to absorb ultra-violet light at 240 m $\mu$ . Estimates of relative rates of *de novo* synthesis of these steroids, as well as of cholesterol (both free and esterified), were made by measuring the carbon-14 content of these compounds after purification by thin-layer chromatography followed by enzyme reduction<sup>1</sup> and/or recrystallization of progesterone; acetylation and rechromatography of 20 $\alpha$ -hydroxy-pregn-4-en-3-one; and bromination, rechromatography, and debromination of free and ester cholesterol<sup>5</sup>.

The ability of luteinizing hormone to stimulate the *in vitro* synthesis of progesterone and 20 $\alpha$ -hydroxy-pregn-4-en-3-one equally well in the presence of AY9944 as in its absence is shown in Table 1. Specific radioactivities obtained in the same experiments (Table 2) revealed that AY9944 very markedly decreased the *de novo* synthesis of these steroids from acetate-1-<sup>14</sup>C.

The ability of the inhibitor to decrease the rate of cholesterol synthesis is illustrated in Table 3. This effect, which applies both to free and to esterified cholesterol, did not apply to lipids as a whole. Fatty acid specific activities of all ovarian lipids except sterol esters were essentially unchanged by AY9944 and luteinizing hormone.

Of considerable interest was the observation that while the incorporation of acetate carbon into the steroid hormones analysed was increased by luteinizing hormone, this incorporation frequently did not keep pace with the increased net synthesis (mass) of these steroids. Furthermore, the incorporation of acetate carbon into cholesterol, especially the esterified fraction, was decreased by luteinizing hormone. It is difficult to reconcile these results with the hypothesis of Savard *et al.*<sup>3</sup> that luteinizing hormone brings about increased steroidogenesis to a significant extent by increasing the rate of synthesis of cholesterol. The observations could be more readily interpreted as favouring the alternative proposal of Mason and Savard<sup>6</sup> that luteinizing hormone "acts primarily to stimulate the formation of steroid from precursors which are earlier (than cholesterol) in the biosynthetic scheme". By-passing cholesterol, were it not for the present finding that the inhibitor AY9944 greatly decreased the incorporation of acetate carbon into the progestins synthesized in response to luteinizing hormone without affecting the mass synthesized.

These results indicate that in the rabbit ovarian interstitial gland, luteinizing hormone stimulates steroidogenesis (progesterone and 20 $\alpha$ -hydroxy-pregn-4-en-3-one)

Table 1. EFFECT OF LUTEINIZING HORMONE AND OF AY9944 ON NET *in vitro* SYNTHESIS OF PROGESTERONE AND 20 $\alpha$ -HYDROXY-PREGN-4-EN-3-ONE BY RABBIT INTERSTITIAL TISSUE SLICES

† Specific activities determined after single dimensional TLC on silica gel\*, followed by saponification and purification of the resulting cholesterol by the methods for free cholesterol.

*in vitro* equally well whether *de novo* cholesterol synthesis occurs or not.

In the presence of inhibitor the incorporation of acetate carbon into these steroids and into cholesterol is diminished: this indicates that cholesterol is an obligatory intermediate in the biosynthesis of ovarian progestins, as has been demonstrated previously for adrenal<sup>7</sup> and testicular<sup>8</sup> steroids. The evidence as a whole shows that the principal (if not the sole) action of luteinizing hormone in acutely increasing the synthesis of progestin in rabbit ovarian tissue is exerted at a point subsequent to the biosynthesis of cholesterol.

### Glucose and RNA Synthesis in Mammalian Islets of Langerhans

It is well known that glucose stimulates the release of insulin from the mammalian pancreas. It has recently been shown, *in vitro*, that glucose and mannose, but not a non-metabolized sugar such as galactose, will also

stimulate insulin synthesis<sup>1</sup>. We have investigated the effects of glucose on the putative preceding stage, namely, the formation of new messenger RNA, using isolated islets of Langerhans from the duct-tied pancreas of the rat<sup>2,3</sup>. As the amount of tissue available for a given experiment is small (approximately 100  $\mu$ g dry weight), we have investigated the incorporation of 6- $^{14}$ C-uracil into total nucleic acids of the islets.

Islets were incubated in 0.25 ml. Krebs-Ringer bicarbonate buffer<sup>4</sup> containing varying concentrations of glucose, crystalline bovine albumin (2 mg/ml.) and 6- $^{14}$ C-uracil (15  $\mu$ Ci/ml.), with a gas phase of 95 per cent oxygen/5 per cent carbon dioxide. Incubations were carried out in a shaking water bath, at 37° C, for 4 h. At the end of the incubation the islets were transferred to homogenizing tubes, containing 1 ml. of ice-cold 15 per cent trichloroacetic acid. After homogenization, 25 mg crystalline bovine albumin and 3.0 mg of crystalline RNA were added and the whole extracted by the method of Wool and Moyer<sup>5</sup>. Preliminary experiments showed that this method gave recoveries of added RNA of 90–100 per cent. The final product, sodium ribo- and deoxyribo-nucleates, was suspended in phosphor (PPO 4 per cent, POPOP 0.01 per cent in toluene) and counted in an automatic liquid scintillation counter.

Table 1. EFFECT OF GLUCOSE CONCENTRATION ON THE INCORPORATION OF 6- $^{14}$ C-URACIL INTO TOTAL NUCLEIC ACIDS OF ISOLATED ISLETS OF LANGERHANS

Glucose concentration (mg/ml.)	Counts per 20 min minus background in total nucleic acids		
	1	2	3
3.0	2,964	3,119	1,074
1.0		2,236	925
0.15	286	1,295	391
0			540
No. of islets per incubation	25	26	21

Table 1 shows the results of three separate experiments in which incorporation of labelled uracil into nucleic acid was compared at various concentrations of glucose. Clearly, raising the glucose concentration from 0.15 mg/ml. to 1.0 or 3.0 mg/ml. greatly increases the amount of incorporation. Whether there is a real increase when the glucose concentration is raised from 1.0 to 3.0 mg/ml. is not apparent from this small number of experiments. It is, however, clear that increased incorporation is related to the concentration of glucose and not simply to its provision as an energy source. Stimulation of

nucleic acid synthesis by glucose has previously been demonstrated only in thyroid slices, *in vitro*<sup>6</sup>. In these experiments, the effect of glucose was "all or none" and not related to concentration. In our control experiments, using small pieces of the fibro-fatty tissue, which replaces the pancreatic acinar tissue in animals with ligatured pancreatic ducts, and also with rat hemidiaphragms, glucose had no effect on the incorporation of labelled orotic acid into nucleic acids.

The specificity of these findings was checked in the following experiment. Two batches of forty-five islets were incubated at a glucose concentration of 3 mg/ml., one of them in the presence of actinomycin D (5 µg/ml.). The extracted nucleates from each were divided into two aliquots and taken up in 1.0 ml. of *tris* buffer (pH 7.5). 0.1 µg of pancreatic ribonuclease (RNase) was added to one each of the paired aliquots and all four incubated in a shaking water bath at 37° C for 1 h. At the end of the incubation the nucleates were re-precipitated with ethanol and counted. The results are shown in Table 2. In the presence of actinomycin D, no incorporation of orotic acid was detected. Incubation for 1 h with RNase lowered the recovered radioactivity by more than 80 per cent. These two findings strongly support the thesis that the product being measured is, in fact, labelled RNA, as might reasonably be expected when using labelled orotic acid as a precursor.

Table 2. EFFECT OF ACTINOMYCIN D (5 µg/ML.) ON THE INCORPORATION OF 6-<sup>14</sup>C-OROTIC ACID INTO TOTAL NUCLEIC ACIDS OF ISOLATED ISLETS OF LANGERHANS AND THE EFFECT OF RNase ON THE RECOVERY OF RADIOACTIVITY FROM THE PRODUCT

Medium	Glucose 3 mg/ml. Counts per 20 min	Glucose 3 mg/ml. and actinomycin 5 µg/ml. minus background
Without RNase	1,415	0
With RNase	255	0

Whether other carbohydrates can provide the stimulus to RNA synthesis and whether the effect of glucose can be reproduced by simpler energy sources is at present under investigation.

## RADIOBIOLOGY

### Enhancement of the Post-irradiation Protective Action of TAB by an $\alpha$ -Adrenergic Blocking Agent

GRAM-NEGATIVE endotoxins<sup>1</sup> or typhoid-paratyphoid A and B vaccine (TAB)<sup>2</sup> can have a favourable influence on the acute radiation syndrome when they are administered after total-body irradiation. By stimulating excessively the release of adrenergic neurohormones<sup>3,4</sup> or by increasing sensitivity to catecholamines<sup>7,8</sup>, however, these substances can cause reduced blood flow to the kidneys, liver and intestines<sup>5</sup> leading to ischaemia and irreversible tissue damage. Such changes may result from the vasoconstrictor action of catecholamines.

The vasoconstrictor action of the adrenergic neurohormones results from their interaction with the  $\alpha$ -receptors of the adrenergic nervous system<sup>9</sup>. Assuming that the full benefits of TAB treatment might not be obtained because of side effects, presumably related to reduced tissue perfusion, this investigation was designed to determine whether the radioprotective action of TAB could be enhanced through treatment with a pharmacological agent the principal action of which was  $\alpha$ -adrenergic blockade.

Female  $C_3H \times AKR$  mice (9–11 weeks old) were exposed to total-body doses of radiation (300 kVp X-rays; half value layer 1.7 mm copper; 19.5 amp current; 110 rads/min). The mice were distributed among three experimental groups. Group I received X-irradiation only. One hour after irradiation, Group II received an intraperitoneal injection of TAB containing  $3.3 \times 10^8$  killed organisms of *Salmonella typhi* and  $1.7 \times 10^8$  organisms each of *Salmonella paratyphi A* and *Salmonella paratyphi B*. Group III received X-irradiation, TAB and, starting 1 h after TAB, the reversible  $\alpha$ -adrenergic blocking agent phentolamine methane sulphonate (PMS), 5 mg per kg body weight, subcutaneously. PMS was given twice daily for 3.5 days; the twice daily injections were separated by about 8 h. The mice in Groups I and II received comparable volumes of pyrogen-free physiological saline.

At the end of a 30 day observation period, a chi-squared ( $\chi^2$ ) test for the difference between proportions was used to determine the significance of differences between the proportion of animals dying in the various groups. Probability values less than 0.05 were taken to represent significant differences. The  $\chi^2$  test was also used in determining the effect of PMS on the time-pattern of death of mice previously exposed to 750 rads total body irradiation and treated with TAB vaccine.

Treatment with TAB had immediate effects on the mice. For about 15–30 min after injection they showed excitation and became very aggressive towards one another. Some animals showed evidence of lacrimation. This phase of excitation and lacrimation was followed by several hours during which the mice remained almost motionless and with their eyelids closed. Some animals had episodes of defecation which almost approached diarrhoea. Within 12–24 h, the mice appeared to recover to normal behaviour. All mice, however, showed a 10–20 per cent loss of weight at 24 h after treatment with TAB. Thereafter, no other symptoms were observed that could be attributed directly to treatment with TAB.

Table 1 shows the mortality following the various treatments. At all radiation doses tested, TAB vaccine alone significantly reduced mortality below that of control mice ( $P < 0.001$ ). PMS significantly reduced mortality below that of mice treated with TAB ( $P < 0.05$  at the 700 rad level, and  $P < 0.005$  at the 750 rad level). Table 2 shows the influence of PMS on the time of death of mice exposed to 750 rad and treated with TAB. The effect of PMS in reducing mortality was most significant during the third week after irradiation. During this time, the death rate of animals treated with TAB was reduced by PMS from 67 to 32 per cent ( $P < 0.01$ ). No significant

Table 1. THIRTY-DAY MORTALITY OF  $C_3H \times AKR$  MICE

Radiation dose (rad)	Control	Treatment TAB	TAB + PMS
600	*16/40 (40)	—	—
650	38/56 (68)	1/33 (2.8)	—
700	62/64 (97)	22/40 (55)	11/40 (28)
750	67/67 (100)	50/60 (83)	34/60 (57)

\* Number dead/number treated (percentage mortality).

Table 2. EFFECT OF PMS ON TIME PATTERN OF RADIATION DEATH  
Weeks after 750 rads total-body irradiation

Treatment	First	Second	Third	Fourth
TAB	*0/60 (0)	30/60 (50)	20/30 (67)	0/10 (0)
TAB + PMS	0/60 (0)	20/60 (33)	13/40 (32)	1/27 (3.5)

\* Number dead during period/number entering period (percentage mortality).

differences in percentage mortality were observed during the first, second and fourth weeks after irradiation.

These results show that the protective action of TAB vaccine after irradiation may be enhanced by an agent the principal pharmacological action of which is  $\alpha$ -adrenergic blockade. Although it is not yet possible to exclude other pharmacological effects of PMS as being responsible for this enhancement, it is tentatively postulated that PMS exerts this action by blocking the effect on  $\alpha$ -adrenergic receptors of catecholamines released by TAB vaccine. The protective action of PMS was most apparent during the third week after irradiation, although PMS was administered for 3.5 days immediately following TAB. It appears that changes may be produced by TAB immediately after its administration which contribute to radiation mortality several weeks later, and that these changes (presumably related to tissue perfusion) are modified favourably by PMS.

These results may also suggest a possible mechanism for the radioprotective action of TAB and Gram-negative endotoxin. Shock, whether of haemorrhagic or bacteriaemic origin, is the main cause of death after exposure to potentially lethal doses of ionizing radiations. Catecholamines released in excessive quantities are thought to play a principal part in the mediation of bacteriaemic and haemorrhagic shock<sup>8,10</sup>. As catecholamines may only be slowly replaced in tissues after their release<sup>11-13</sup>, sub-lethal doses of endotoxin or TAB may deplete tissues of their catecholamines so that the quantities of free catecholamines required to produce irreversible shock may not be available during the haemorrhagic and/or bacteriaemic phases of the acute radiation syndrome. This hypothesis for the mechanism of action of TAB vaccine and Gram-negative endotoxins, including the postulated role of PMS, is illustrated in Fig. 1. As other substances are known to release catecholamines from tissues and as methods are available for the estimation of catecholamines in tissues<sup>14</sup>, the validity of this hypothesis can be tested. Should this mechanism prove to be a chief component of the action of TAB or endotoxin, then the depletion or partial reduction of catecholamines (or other potential shock substances) from tissues in the presence of  $\alpha$ -adrenergic blockade may represent an important preparation of irradiated subjects for entry into those phases of the acute radiation syndrome which lead easily to irreversible shock.

A more rapid recovery of haemopoietic tissues is often noted after total-body irradiation when this follows treatment with either TAB vaccine or Gram-negative endotoxins<sup>3,4</sup>. This effect need not be due to a direct action of these substances on organs which form blood cells. Any treatment which eventually reduces the

occurrence of either reversible or irreversible shock may make possible a more complete repair of tissues damaged by radiation.

### Inhibition of Stromal Enzymes by X-Radiation

HIGH doses of X-radiation appear to alter the function of the erythrocyte membrane without producing much change in the internal metabolism of cells<sup>1</sup>. In order to define the changes which occur in the erythrocyte membrane more precisely, we have investigated the effects of X-rays on various enzymes in isolated stroma. Marked differences in the radiosensitivity of these enzymes were observed (Table 1).

Dose-effect curves for the most radiosensitive of these enzymes, the acid phosphatase, are shown in Fig. 1. Measurable inhibition of this enzyme was observed with radiation doses as low as 4 krad but the inhibition tended to approach a maximum value of 65 per cent as the radiation dose was increased up to 400 krad. Storage of the irradiated stroma at 4° C did not result in recovery but rather in further degeneration of the enzyme activity (Fig. 1). Qualitatively similar results were observed with nucleoside phosphorylase and acetylcholinesterase but not with the four other enzymes tested.

The inhibition of enzyme by X-irradiation has frequently been attributed to the oxidation of sulphhydryl groups. The total sulphhydryl content of the stroma, measured with dithiobis-(2-nitrobenzoic acid) in the presence of sodium dodecyl sulphate<sup>2</sup>, was found to decrease slowly with increasing doses of X-radiation (Fig. 1). This decrease in sulphhydryl, however, could not account for the differential radiosensitivity of the stromal enzymes. When stromal suspensions were pre-incubated for 1 h at 37° C with 0.03-3 mmolar *p*-chloromercuribenzoate or *N*-ethylmaleimide to block the sulphhydryl groups, the activity of radio-resistant adenosine-tri-phosphatases (ATPases) was more strongly inhibited than that of a radiosensitive enzyme such as acid phosphatase. Oxidative reagents, that is, iodine and hydrogen peroxide, had a similar effect. It seems unlikely, therefore, that the effect of X-radiation on stromal enzymes (Table 1) could be attributed primarily to oxidative reactions.

Enzyme inhibition by reduction of -S-S bridges during irradiation has also been

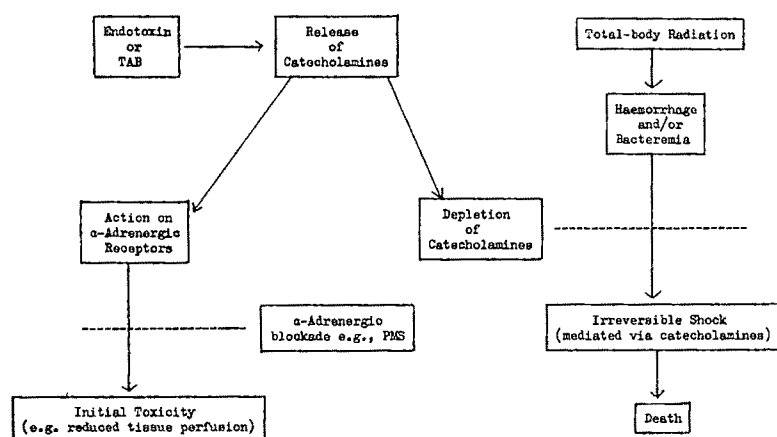

Fig. 1. Hypothesis for the radioprotective effect of TAB vaccine and Gram-negative endotoxins, and the postulated mechanism whereby PMS enhances their radioprotective action; explanation in text.

Fig. 1. Inhibition of the acid phosphatase activity of stromal suspensions following X-irradiation. Enzyme activities were measured immediately after X-irradiation (●) and after storing the same suspensions for 2 days at 4° C (○). The total sulphydryl content of the stromal protein (Δ) was also measured immediately after irradiation.

Table 1. EFFECT OF X-RADIATION ON STROMAL ENZYMES

	Enzyme activity (per cent control values)	
	64 krad	200 krad
Ouabain-sensitive ATPase <sup>a</sup>	109	102
Ouabain-resistant ATPase <sup>a</sup>	104	98
Diphosphoglycerate phosphatase <sup>b</sup>	120	—
Aldolase <sup>c</sup>	82	68
Nucleoside phosphorylase <sup>d</sup>	63	28
Acetylcholinesterase <sup>e</sup>	62	35
Acid phosphatase <sup>f</sup>	56	37

Erythrocyte stroma were recovered from a haemolysate of washed rat erythrocytes by centrifugation for 30 min at 3,000g and 4° C. The stroma were washed three times and finally suspended in 4 volumes of 1 mmolar ethylenediaminetetraacetate at pH 7.4. Samples of this suspension were irradiated (16 krad/min)<sup>g</sup> at 0° C in the presence of air and assayed for enzyme activity. The methods of assay are indicated by the references listed above.

reported<sup>9</sup>. In our experiments, the effects of X-rays on stromal enzymes could be partly reproduced with reducing agents, that is, sodium dithionite, mercaptoethylamine, and dithiothreitol. After incubation of stroma with 1 mmolar dithiothreitol<sup>10</sup> for 1 h at 37° C and pH 7.4, for example, the ouabain-sensitive ATPase, the ouabain-resistant ATPase and the acid phosphatase activities were 138, 103 and 54 per cent of the control values. The data thus suggest that part of the radiation effect on stromal enzymes may be caused by reduction of —S—S bridges and subsequent disruption of protein structure.

with a deposit of manganese dioxide. Manganese-54 has been present in rain water in significant concentrations since the Soviet nuclear test series of 1961 (ref. 1) and samples of used filter bed material have been examined for their radiomanganese content. This particular material resulted from the filtration of a colourless moorland water at high pH and the process effectively removes the 0.25 p.p.m. of manganese present.

A preliminary examination of the material of the filter bed showed that the sand particles had been coated with manganese dioxide containing smaller amounts of aluminium, calcium, iron and magnesium. The coated grains were almost spherical and of uniform size. The manganese-54 content was 458 pc./g corrected for radioactive decay to the time of sampling (17.9.65). It was found possible to remove successive layers from the grains by abrasion. The manganese content of each layer was sensibly constant (60 per cent as manganese dioxide), but the specific activity of the manganese-54 decreased towards the centre of the coated grains. Twenty-two layers representing about 40 per cent of the coating were removed. Fig. 1 shows the reduction of the specific activity of the manganese in the successive layers.

Fig. 1. Distribution of manganese-54 within the coated filter bed material. (The numbers on the graph relate to the layer removed.)

The initial part of the curve is straight. The subsequent curvature could be accounted for by a period of enhanced deposition of manganese-54 in fall-out such as occurred after the Soviet tests of 1961. Although it was known that the sand filter had been in use for about 10 years it was not found possible to relate a specific layer to a specific date.

Because manganese dioxide is known to absorb radionuclides derived from fall-out from water<sup>2</sup>, the filter bed material was examined for such radionuclides. The results are shown in Table 1. Because no atmospheric tests had taken place for 20 months before sampling, no short-lived radionuclides were expected or found. The radionuclides of highest activity were those of cerium, promethium and ruthenium, which would be expected to be coprecipitated with manganese. The concentration of caesium-137 was low and that of strontium-90 intermediate. Neither of the

## APPLIED SCIENCE

### Accumulation of Radionuclides in Water Works Filter Bed Material

THE presence of manganese in certain water supplies is an inconvenience which can lead to the formation of deposits and, in extreme cases, to blockage of the mains. Several water undertakings introduce a special precipitation and sand filtration process to remove it. The sand of the filter beds at such undertakings becomes coated

Table 1. FALL-OUT RADIONUCLIDES IN COATED FILTER BED SAND

Radionuclide	Activity* pc./g of coated sand
Strontium-90	13.8
Yttrium-90	13.8
Yttrium-91	N.S. < 0.1
Zirconium-95	N.S. < 0.1
Ruthenium-106/rhodium-106	27.4
Tellurium (total)	0.2
Antimony-125	< 0.4
Caesium-137	2.8
Cerium-144	17.0
Praseodymium-144	17.0
Promethium-147	29.1

N.S., Not significant.

\* Activities corrected for decay to 17.9.65.

Fig. 2. Gamma-spectrum of coated filter bed material.

two latter radionuclides was likely to have been co-precipitated as hydroxides with the manganese and their presence in the material was probably due to their sorption from the water.

At this stage, total  $\alpha$ - and  $\beta$ -determinations on samples of the coated sand revealed that a major part of the radioactivity was still unaccounted for—in fact, three-quarters of the total  $\beta$ -activity of 490 pc./g. In view of this, and of the considerable total  $\alpha$ -activity present (840 pc./g) we considered the probable presence of naturally occurring radionuclides. A qualitative  $\gamma$ -spectrometric analysis (Fig. 2) confirmed this.

By estimating certain radionuclides it was found possible to build up a fairly complete picture of the concentrations of each of the natural radioactivities in the coated sand. It was assumed that because the time elapsed between the collection of the sample and its examination for natural radioactivity was more than 1 year, any radioactive daughters in either the thorium or uranium series of half-life 50 days or less would be in radiochemical equilibrium with their parents. Thus, protoactinium-234 and thorium-234 would have been in radiochemical equilibrium with uranium-238, radium-224 with thorium-228 and radium-224 and -226 likewise with their respective daughter products if the assumption can be made that the gaseous thoron (radon-220) and radon (radon-222), respectively, were held by the coating. This was shown to be substantially the case by an experiment in which air was passed continuously through some coated sand for 16 h and a reduction of only 20 per cent in the concentration of radium daughters took place. Considerably less thoron and radon would be expected to be released under normal conditions of storage. Table 2 lists the concentrations of those naturally occurring radionuclides in the coating determined experimentally.

A qualitative  $\alpha$ -spectrometric analysis, using a solid state silicon detector and a multichannel analyser, on a chemically separated thorium fraction shows that thorium-232 and -230 were absent. Fig. 3 shows the  $\alpha$ -spectrum of this thorium fraction approximately 2 days after separation from a sample of the coating. The daughters of thorium-228 were beginning to build up. Thorium-232 and -230 if present would have occurred in the neighbourhood of channels 14 and 22, respectively. Because thorium-232 was virtually absent, the thorium-228 concentration, calculated from that of its radium-224 daughter, must have arisen from its parent radium-228. Radiochemical equilibrium between radium-228 and thorium-228 would

Fig. 3. Alpha-spectrum of thorium fraction separated from coated filter bed material.

take some years to become established, and as the figures in Table 2 show, this had only proceeded half way. Apart from the naturally occurring radionuclides, considerable radioactivity due to plutonium (-239 and -240), previously reported in fall-out<sup>3</sup>, was detected. The plutonium was presumably unfissioned material originating from nuclear devices exploded in the atmosphere. The presence of plutonium in the coating suggested that uranium-235, the other common fissionable material, might also be present in the coating. A radioassay on the chemically separated uranium, however, showed an equivalence with the colorimetric determination of the element which confirmed the presence of natural uranium with no additional content of uranium-235.

It can be inferred from the concentrations of the natural activities present in the coating that the main radionuclides present in the raw water were those of uranium, radium and plutonium, thorium being absent.

The activities of the various  $\alpha$ - and  $\beta$ -emitting daughter products not experimentally determined were deduced from the concentrations of the parent radionuclides in Table 2. From all these results, together with those from Table 1, separate inventories of the  $\alpha$ - and  $\beta$ -emitting radionuclides present in the coating were made. The inventory of all the  $\beta$ -emitters, both fall-out and naturally occurring, present in the coating gave a summed activity of 493 pc./g. This compared favourably with the measured total  $\beta$ -activity of 490 pc./g, both summed and total activities being calculated with respect to a strontium-90 standard at 17.9.65. This close agreement was perhaps fortuitous, but did serve to show that no principal  $\beta$ -emitters had been omitted from the inventory. The agreement between the total  $\alpha$ -activity found, 840 pc./g, and the sum of the individual  $\alpha$ -emitting radionuclides found, 775 pc./g, all activities being calculated with respect to a natural uranium standard at 17.9.65, was also considered satisfactory.

We thank Mr. A. B. Baldwin, general manager and engineer, Sheffield Corporation Waterworks, for providing the samples for this investigation and for suggesting that we study the deposition of manganese-54 within the filter bed sand coating. We also thank Dr. D. I. Coomber for his helpful advice.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, February 13

INSTITUTE OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "The Impact of Integrated Circuits on the Role of the Circuit Designer", opened by Mr. A. G. I. Cressell and Mr. R. Towell.

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (Joint meeting with the Colloid and Surface Chemistry Group, at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Prof. A. E. Alexander: "The Role of the Surfactant in Heterogeneous Polymerization".

UNIVERSITY OF LONDON (at Bedford College, Regent's Park, London, N.W.1), at 6 p.m.—Prof. A. Williams: "British Ordovician Shelly Faunas. III, Implications of Faunal Distributions".\*

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W.3), at 6.15 p.m.—Dr. M. K. Towers: "Cardioversion and Control of Arrhythmias".\*

## Tuesday, February 14

INSTITUTE OF CHEMICAL ENGINEERS, SOUTH EASTERN BRANCH (at the Royal Aeronautical Society, 4 Hamilton Place, London, W.1), at 11 a.m.—Symposium on "Chlorine in Industry".

ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

INSTITUTE OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Dr. B. J. Mason: "Recent Developments in Weather Forecasting and their Application to Industry" (James Forrest Lecture).

INSTITUTE OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. J. C. West, Dr. B. V. Jayawant and Mr. D. P. Rea: "Transition Characteristics of the Jump Phenomenon in Nonlinear Resonant Circuits".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Prof. R. L. F. Boyd: "The Scientific Role of Man in Space" (Lecture for Sixth Form Boys and Girls from Schools in London and the Home Counties. To be repeated on February 15, 21 and 22.)

UNIVERSITY OF ASTON IN BIRMINGHAM (in the Great Hall of the University, Gosta Green, Birmingham 4), at 5.30 p.m.—Prof. Gibson: "Universities and the Managerial Revolution" (Inaugural Lecture).\*

UNIVERSITY OF LONDON (at Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. B. R. Coles: "Solid State Physics—In Particular Metals" (Inaugural Lecture).\*

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Dr. A. C. Allison: "Lysosomes". (Tenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

UNIVERSITY OF LONDON (in the Anatomy Theatre, King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. H. Kellenberger (Geneva): "Studies on the Morphogenesis of the Head of Bacteriophage T4".\*

INSTITUTE OF THE RUBBER INDUSTRY, LONDON SECTION (at the Eccleston Hotel, Victoria, London, S.W.1), at 5.30 p.m.—"Technology and Uses of the Newer Types of Carbon Black" by a speaker from Cabot Carbon, Ltd. 7 p.m.—Mr. F. W. Gage: "Rubber to Metal Bonding".

## Wednesday, February 15

CHEMICAL SOCIETY (in the Chemistry Lecture Theatre, Imperial College of Science and Technology, London, S.W.7), at 2.30 p.m.—Organic Chemistry Symposium. Prof. B. G. L. Weedon: "Recent Advances in the Carotenoid Field"; Prof. A. W. Johnson: "Macrocyclic Tetrapyrrole Compounds"; Prof. D. H. R. Barton: "A Region of Biosynthesis".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. F. H. Bushby and Mr. M. S. Timpon: "A Ten-Level Atmospheric Model and Frontal Rain"; Mr. R. F. Zobel: "Temperature and Humidity Changes in the Lowest Few Thousand Feet of Atmosphere".

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. V. D. Barnett: "Assessment of Low Temperature Probabilities throughout Great Britain".

INSTITUTE OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "Possible Alternatives to Copper" opened by Mr. E. H. Reynolds.

UNIVERSITY OF LONDON (at Senate House, London, W.C.1), at 5.30 p.m.—Prof. Suzanne Mansion: "Plato's Conception of the Intelligible. II. Mathematics and Dialectics".\*

INSTITUTE OF ELECTRONIC AND RADIO ENGINEERS, RADAR GROUP (at 8-9 Bedford Square, London, W.C.1), at 6 p.m.—Mr. A. C. McKellar and Mr. M. J. Dilworth: "The Remote Control of Lighthouses and Beacons".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. Arthur Southway: "British Printing Machinery".

SOCIETY FOR ANALYTICAL CHEMISTRY, RADIOCHEMICAL METHODS GROUP (at the Borough Polytechnic, Borough Road, London, S.E.1), at 6.30 p.m.—Dr. E. S. Williams: "The Basic Principles of Dilution Analysis, Activation Analysis, Derivative Analysis, Saturation Analysis and Immuno-assay in a Medical Context"; Dr. G. E. Harrison: "The Uses of Radioactive Markers in the Study of Mineral Metabolism with special reference to the Alkaline Earths".

INSTITUTE OF FUEL (at Croydon Technical College, Fairfield, Croydon, Surrey), at 7 p.m.—Mr. P. F. Corbett: "Natural Gas in Europe".

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN AND THE BOTANICAL SOCIETY OF THE BRITISH ISLES (at 17 Bloomsbury Square, London, W.C.1), at 7 p.m.—Dr. T. D. Whitte: "Some Early Apothecary Botanists"; Mr. D. E. Allen: "The Origins of British Field Botany".

## Wednesday, February 15—Thursday, February 16

INSTITUTE OF PHYSICS AND THE PHYSICAL SOCIETY, ELECTRON MICROSCOPY AND ANALYSIS GROUP, in association with the INSTITUTE OF METALS and the IRON AND STEEL INSTITUTE (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2)—Conference on "Recent Developments in the Theory, Technique and Application of Electron Probe Microanalysis".

## Thursday, February 16

SOCIETY OF INSTRUMENT TECHNOLOGY (at the Town Hall, Middlesbrough), at 9.30 a.m.—Symposium on "The Presentation of Data".

SOCIETY FOR ANALYTICAL CHEMISTRY, BIOLOGICAL METHODS GROUP (at the Pharmaceutical Society, 17 Bloomsbury Square, London, W.C.1), at 2.30 p.m.—Meeting on "The Microbiological Determination of the Nutritive Value of Proteins". Speakers will include: Mr. J. E. Ford, Mr. W. S. Miller and Mr. J. A. Stott.

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (at 14 Belgrave Square, London, S.W.1), at 2.30 p.m.—Meeting on "Adhesives in Building". Mr. W. C. Wake: "The Types and Uses of Adhesives in Building"; Mr. R. T. Kelly and Mr. A. M. Berman: "Adhesives in Building".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. D. O. Hayward, Mr. D. A. King and Prof. F. C. Tompkins F.R.S.: "Sticking Probabilities, Redistribution Processes and Desorption Spectra of Nitrogen on Tungsten Films"; Mr. M. A. A. Clyne, Mr. D. B. Hartley and Mr. B. A. Thrush: "Direct Determination of the Rates of Elementary Processes in the Hydrogen-Oxygen Reaction".

UNIVERSITY OF LONDON (at King's College Hospital Medical School, Denmark Hill, London, S.E.5), at 4.45 p.m.—Prof. H. C. Killey: "Fractures of the Middle Third of the Facial Skeleton" (19th Thomas Percy Legg Memorial Lecture).\*

INSTITUTE OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. C. C. Dell and Dr. J. Sinha: "Experimental Study of the Behaviour of Flocculated Clays in Thickening"; Mr. K. J. Scott and Mr. J. L. Alderton: "Maximum Solids Handling Capacity of Continuous Thickeners"; Mr. E. Douglas and Mr. T. Walsh: "New Type of Dry, Heavy-Medium, Gravity Separator".

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. G. S. Carter: "Polyphyletism and Vertebrate Evolution"; Dr. C. A. Wright: "The Molluscan Genus *Bulinus*; a Study in the Evolution of Taxonomic Methods".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. I. G. Macdonald: "Spherical Functions".

UNIVERSITY OF LONDON (at the Royal Veterinary College, Royal College Street, London, N.W.1), at 5 p.m.—Dr. J. M. Barnes: "Fungal Toxins with special reference to Aflatoxin".\*

UNIVERSITY OF LONDON (in the Eugenic Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Prof. Charles Rousseau (Paris): "Scientific Progress and International Law".\*

INSTITUTE OF PETROLEUM, EXPLORATION AND PRODUCTION GROUP (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. J. van Dam: "Gas Production from the Producers' Viewpoint".

INSTITUTE OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal discussion on "Build Landour Systems and their Effect on Airport Design" introduced by Mr. O. B. St. John.

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Prof. George Dick: "Immunization Against some Virus Diseases". (Eleventh of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

INSTITUTE OF ELECTRICAL ENGINEERS (at the Central Hall, Westminster, London, S.W.1), at 6 p.m.—Mr. R. V. Moore: "Nuclear Power Today and Tomorrow" (Faraday Lecture).

OIL AND COLOUR CHEMISTS ASSOCIATION, LONDON SECTION (in the Physics Department, Imperial College, London, S.W.7), at 6.30 p.m.—Dr. A. C. Healey: "The Printing of Bank of England Notes".

UNIVERSITY OF LONDON (at Wye College, near Ashford, Kent), at 8.15 p.m.—Prof. H. Bondi, F.R.S.: "Science and Education".

## Friday, February 17

BIOCHEMICAL SOCIETY (at St. Mary's Hospital Medical School, Paddington, London, W.2)—468th Meeting. Programme will include a Colloquium on "Mechanisms of Biological Hydroxylation".

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W.1), at 1 p.m.—Dr. A. Knowles: "Photochemistry of Flavins".

INSTITUTE OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "High-Pressure Gas Breakdown" opened by Dr. A. H. Cookson and Mr. G. F. Goldspink.

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Prof. Jean Frezal (Paris): "The Implication of Physiological Genetics in the Study of Inborn Errors in Man".\*

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN and the BRITISH ACADEMY OF FORENSIC SCIENCES (at the School of Pharmacy, University of London, Brunswick Square, London, W.C.1), at 6 p.m.—Mr. T. E. A. Carr, Mr. A. D. Oxford, Mr. J. Lynch and Mr. R. M. Mitchell: "Forged Prescriptions".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Lord Rothschild, G.M., F.R.S.: "Research in a Very Big Industry".

## Saturday, February 18

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. John F. Potter: "Fossils—Their Preservation and Occurrence".\*

## Monday, February 20

INSTITUTE OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 9.30 a.m.—Colloquium on "Message Switching".

INSTITUTE OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 2 p.m.—Colloquium on "Precision Resistance Standards".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. K. R. Sealey: "The Siting and Development of British Airports".

UNIVERSITY OF LONDON (in the Engineering Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. G. Kendall, F.R.S.: "Delphic Semi-Groups".

Monday, February 20—Tuesday, February 21

INSTITUTION OF ELECTRICAL ENGINEERS (joint symposium with the I.C.E. and the I.Mech.E., at the Institution of Civil Engineers, Great George Street, London, S.W.1)—Symposium on "Area Control of Road Traffic".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER and an ASSISTANT LECTURER in PURE OR APPLIED MATHEMATICS (including numerical analysis and statistics)—The Registrar, The University, Manchester, 13, quoting Ref. 13/67 (February 18).

RESEARCH FELLOW (postdoctoral or equivalent) in the DEPARTMENT OF NATURAL HISTORY to join a team of ecologists studying rook populations—The Secretary, The University, Aberdeen (February 18).

LECTURER or ASSISTANT LECTURER (medically qualified or non-medically qualified) in the DEPARTMENT OF BACTERIOLOGY—The Registrar, The University, Leeds, 2 (February 20).

LECTURER or ASSISTANT LECTURER (preferably with teaching and research interests in genetics, especially the genetics of micro-organisms) in BIOLOGY—The Secretary, University of Stirling, Stirling, Scotland (February 20).

LECTURER or ASSISTANT LECTURER (with research interests in any branch of applied mathematics or mathematical physics) in APPLIED MATHEMATICS—The Registrar, University of York, Heslington, York (February 20).

LECTURER (preferably with an interest in statistics and operational research) in ENGINEERING MATHEMATICS—The Secretary, The Queen's University, Belfast, Northern Ireland (February 20).

LECTURER or ASSISTANT LECTURER (preferably with qualifications in algebra, topology or related subjects) in PURE MATHEMATICS—Head of the Mathematics Department, Imperial College of Science and Technology, London, S.W.7 (February 21).

SENIOR LECTURER (preferably with an interest in the industrial aspects of microbiology) in MICROBIOLOGY—The Registrar, University of Strathclyde, George Street, Glasgow, C.1 (February 21).

LECTURER or ASSISTANT LECTURER in EXPERIMENTAL PHYSICS—The Registrar (Room 39, O.R.B.), The University, Reading (February 24).

UNIVERSITY TUTORS in PHYSIOLOGY—The Secretary, The Queen's University, Belfast, Northern Ireland (February 24).

LECTURER or ASSISTANT LECTURER in APPLIED MATHEMATICS—The Registrar, The University, Hull (February 25).

LECTURER or ASSISTANT LECTURER in the DEPARTMENT OF BIOCHEMISTRY—The Registrar, The University, Hull (February 25).

LECTURER or ASSISTANT LECTURER (with an interest in any field other than hard rock geology) in GEOLOGY—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (February 27).

ASSISTANT LECTURER in ORGANIC CHEMISTRY—The Secretary, The Queen's University, Belfast, Northern Ireland (February 28).

ASSISTANT LECTURER in the DEPARTMENT OF ZOOLOGY—The Secretary, University College London, Gower Street, London, W.C.1 (February 28).

CHAIR OF SOCIOLOGY at the University of Ghana—The Assistant Registrar, Universities of Ghana Office, 15 Gordon Square, London, W.C.1; or The Registrar, University of Ghana, P.O. Box 25, Legon, Accra, Ghana (February 28).

LECTURER in PSYCHOLOGY in the DEPARTMENT OF PHILOSOPHY—The Registrar, University College of Wales, Aberystwyth (February 28).

LECTURER or ASSISTANT LECTURER in MATHEMATICAL PHYSICS—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (February 28).

ASSISTANT LECTURER or LECTURER (preferably with interests in locational studies) in the DEPARTMENT OF GEOGRAPHY in the field of economic geography—The Secretary, Faculty of Geography and Geology, Sedgwick Museum, The University, Cambridge (March 1).

LECTURER or ASSISTANT LECTURER (with a degree in physics, chemistry, metallurgy or engineering and research experience in one or more branches of materials science) in ENGINEERING MATERIALS—The Deputy Secretary, The University, Southampton (March 1).

SENIOR DEMONSTRATOR in CHEMISTRY—The Registrar, University of Durham, Old Shire Hall, Durham (March 1).

RESEARCH ASSISTANT (with a degree in botany or a related subject or substantial palynological experience) in PALYNOLOGY in the DEPARTMENT OF GEOGRAPHY in the Research School of Pacific Studies, Australian National University, to carry out the pollen analysis of Cenozoic (mainly Quaternary) sediments and similar work in collaboration with Dr. D. Walker—The Registrar, Institute of Advanced Studies, Australian National University, Box 4, P.O., Canberra, A.C.T., Australia, quoting Ref. No. 67007 (March 3).

SENIOR LECTURER in APPLIED MATHEMATICS in the DEPARTMENT OF APPLIED MATHEMATICS AND COMPUTER SCIENCE—The Registrar, The University, Sheffield (March 3).

LECTURER or ASSISTANT LECTURER in HISTOLOGY and/or NEUROANATOMY in the DEPARTMENT OF ANATOMY—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (March 4).

CHAIR OF ARCHAEOLOGY—The Registrar, The University, Leicester (March 7).

PROFESSOR OF EDUCATION—The Registrar, University of Bradford, Bradford 7 (March 10).

READER in PSYCHOLOGY—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (March 11).

PROFESSOR and HEAD of the DEPARTMENT OF GEOGRAPHY, Makerere University College, University of East Africa—The Inter-University Council, 83 Bedford Place, London, W.C.1 (March 13).

LECTURER (with special qualifications in animal housing and in one or more of the following fields: environmental control systems, environmental physiology and animal behaviour) in the DEPARTMENT OF AGRICULTURE—The Registrar (Room 39, O.R.B.), The University, Reading (March 15).

LECTURER/SENIOR LECTURER (qualified in any branch of psychology) in PSYCHOLOGY at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, March 20).

CHAIR OF PURE MATHEMATICS—The Registrar, The University of Birmingham, P.O. Box 363, Birmingham 15 (May 31).

RESEARCH DEMONSTRATORS (2) (with a good degree in botany or horticulture) in the DEPARTMENT OF HORTICULTURE to assist with practical classes and carry out research in the physiology of horticultural plants or in plant-insect relations—Prof. O. V. S. Heath, F.R.S., University of Reading, Horticultural Research Laboratories, Shinfield Grange, Reading, Berkshire.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

Royal Observatory Bulletins. No. 121: Photoelectric Magnitudes and Colours of Southern Stars, II. By A. W. J. Cousins, R. Lake and R. H. Stoy. Pp. E1-E56. 9s. net. No. 122: Fabry Photometry of Bright Southern Stars. By A. W. J. Cousins. Pp. E57-E124. 9s. net. (London: H.M. Stationery Office, 1966.) [1811]

Scientific and Industrial Measurement and Control: STRA's Contribution to British Industry. Pp. 20. (Chislehurst, Kent: The British Scientific Instrument Research Association, 1966.) [2111]

Philosophical Transactions of the Royal Society of London. Series A: Mathematical and Physical Sciences. No. 1116, Vol. 261 (17 November, 1966): The Heats of Combustion of Graphite, Diamond and Some Non-Graphitic Carbons. By P. Hawtin, J. B. Lewis, N. Moul and R. H. Phillips. Pp. 67-95. 11s.; \$1.65. No. 1117, Vol. 261 (17 November, 1966): Cubic Equations or Additive Type. By Prof. H. Davenport, F.R.S., and D. J. Lewis. Pp. 97-136. 15s.; \$2.25. (London: The Royal Society, 1966.) [2111]

University of Oxford. Report of the Committee on University Libraries. Pp. 210. (Supplement No. 1 to the *University Gazette*, Vol. 97, November 1966.) (Oxford: The University, 1966.) 15s. [2211]

### Other Countries

United States Department of the Interior: Geological Survey. Bulletin 1185-C: The Uraniferous Zirconium Deposits of the Pocos de Caldas Plateau, Brazil. By Gene E. Tolbert. Pp. iv + 28 + plates 1-3. \$0.70. Bulletin 1280-F: Mineral Resources of the Sycamore Canyon Primitive Area, Arizona. By Lyman C. Huff, Elmer Santos and R. G. Raabe. Pp. v + 19 + plate 1. \$0.50. Geophysical Abstracts, No. 237, October 1966. By James W. Clarke, Dorothy B. Vitaliano, Virginia S. Neuschel, and others. Pp. ii + 899-1002. \$0.35. Abstracts of North American Geology, September 1966. Pp. i + 917-1030. \$0.45. Professional Paper 514: Measurement of Hydraulic Diffusivity of Wedge-shaped Aquifers Drained by Streams. By R. W. Stallman and I. S. Papadopoulos. Pp. iii + 60 + plates 1-120. \$4.50. (Washington, D.C.: Government Printing Office, 1966.) [2111]

Rubber Research Institute of Malaya. Annual Report 1965. Pp. 118. (Kuala Lumpur: Rubber Research Institute of Malaya, 1966.) \$3. [2111]

Transactions of the American Philosophical Society, New Series, Vol. 56, Part 5: Mechanical Universe—The Astrarium of Giovanni de' Dondi. By Silvio A. Bedini and Francis R. Maddison. Pp. 69. (Philadelphia: The American Philosophical Society, 1966.) \$2.50. [2111]

Kungl. Svenska Vetenskapsakademien Handlingar. Fjärde Serien. Band 10, Nr. 3: *Protitanochthys* and some other Coccosteomorph Arthrodires from the Devonian of North America. By Roger S. Miles. Pp. 49 + 8 plates. 19.50 Kr. Band 10, Nr. 4: Attonde Jämförelsen Mellan Svenska Riksprototyperna för Metern och Kilogrammet och mynt- och Justeringsverkets Huvuddikare. Av Karl F. Laurell, L. E. Grönkvist och R. Luuk. Pp. 16. 3 Kr. (Stockholm: Almqvist and Wiksell, 1966.) [2111]

Energy R & D and National Progress: Findings and Conclusions. (An Interdepartmental Study.) Pp. vi + 18. (Washington, D.C.: Government Printing Office, 1966.) \$0.15. [2311]

Office of the Registrar General India, Ministry of Home Affairs. Census of India 1961. Monograph No. 1: Scientific and Technical Personnel. By K. Ray. Pp. ix + 88. (Delhi: Manager of Publications, 1966.) Rs. 1.50; 3s. 6d.; \$0.54. [2311]

Canada: Department of Mines and Technical Surveys. Geological Survey of Canada. Bulletin 144: Groundwater Resources of the Coastal Lowland and Adjacent Islands, Nanos Bay to Campbell River, East Coast, Vancouver Island. By B. C. Halstead and A. Treichel. Pp. 42. \$2. Paper 66-2: Report of Activities, November 1965 to April 1966. Edited by R. G. Blackadar. Pp. vi + 73. \$1. Paper 66-4: Abstracts of Publications in Scientific Journals by Officers of the Geological Survey of Canada, 1965. Compiled by S. E. Jenness. Pp. 56. \$0.50. Paper 66-32: Mont Laurier and Kempt Lake Map-Areas, Quebec. By H. R. Wynne-Edwards, A. F. Gregory, P. W. Hay, C. A. Giovannella and E. W. Reinhardt. (A preliminary report on the Grenville Project.) Pp. v + 82. \$1. Paper 66-46: Geochemical Prospecting Research in 1966, Cobalt Area, Ontario. By R. W. Boyle. Pp. 16. \$0.50. (Ottawa: Queen's Printer, 1966.) [2411]

## NUCLEAR WEAPONS NO MORE ?

THE nuclear powers appear to be cheerfully and even unreasonably hopeful of an international agreement to prevent the spread of nuclear weapons. Mr. Kosygin, in London last week, referred on several occasions to the need for an international treaty, and the joint statement put out after his meeting with Mr. Harold Wilson, the British Prime Minister, expressed the hope that a non-proliferation treaty would "be concluded with the least possible delay". Meanwhile, it is clear that the United States and the Soviet Union have agreed on some kind of a draft for an international treaty, and the two countries have been discussing the draft with their military partners. The United States delegate to the North Atlantic Treaty Organization circulated the draft to the other members of the council on February 1, but it remains to be seen whether even this restricted group of nations will be able to agree within itself. Certainly the Federal German Republic has been sufficiently alarmed by some of the implications of the proposed treaty to send Mr. Willy Brandt, the Foreign Minister, to Washington for discussions. And as yet France has not said where she stands. Yet the nuclear powers apparently expect that it will be possible to make progress with the agreement at the next series of meetings of the Disarmament Committee of the United Nations, which meets at Geneva on February 21. Are they being realistic ?

First of all, it is welcome that the nuclear powers should now consider a further measure of arms control, backed up by international agreement, to be urgently desirable. That in itself is a step forward. It is also sensible that they should have singled out the potential proliferation of nuclear powers as an immediate problem, for so it is. Familiarity with nuclear technology is now so widely spread throughout the world that it is steadily becoming easier for nations to think of making weapons for themselves. At the same time, of course, there are natural restraints which limit the pace at which this process happens (see *Nature*, **210**, 1193; 1966). Although nuclear reactors are widely spread, plans for turning fissile material to military ends are not nearly as common. At least a part of the explanation is that the existing nuclear powers have consistently sought, usually with success, to see that technical assistance with nuclear energy does not help friends and allies to become nuclear powers on their own. The principal nuclear powers are now seeking to make explicit this previously tacit agreement. They have no doubt been moved to do so by the recognition that the collective influence of the United States and the Soviet Union, though still powerful, is no longer decisive.

What are the chances of success ? There are signs that the treaty to be put forward at Geneva will be a

simple document, binding nuclear powers not to help in proliferation and non-nuclear powers not to become recipients of military assistance with nuclear weapons, and not to manufacture them on their own account. But this is only a beginning. Steps will have to be taken to ensure that legitimate trade in nuclear materials is not turned to military ends, which implies inspection—at least for the non-nuclear powers. It is also likely that several nations will be unwilling to sign an international agreement until their own security can be assured, possibly by international guarantee; the difficulty here is that every nation at Geneva will have a different need.

But even if problems like these were entirely to be solved, it is unthinkable that the non-nuclear powers will willingly accept a situation in which the existing nuclear powers will be entitled to enjoy in perpetuity an instrument of military policy they deny to others. In other words, it will be good luck bordering on the miraculous if the nuclear powers are able to collect signatures at Geneva without making substantial concessions about their own freedom to accumulate nuclear explosives. Recent preoccupations about defensive missiles will not help but hinder.

There remains the problem of how it will be possible to safeguard the legitimate technological ambitions of industrialized societies within the framework of a non-proliferation treaty. Several sources in the Federal German Republic have been quick to point out, in the past few weeks, that signing the draft treaty would imply that German industry would be denied an opportunity to exploit the most advanced techniques in nuclear energy. Although these arguments have often been over-coloured by political considerations, they deserve to be considered seriously—especially by those who would like to see a treaty of some sort signed. There is a real conflict to be ironed out. Difficulties could, for example, arise from an attempt by a non-nuclear power to manufacture enriched uranium as a fuel for a fast reactor, or from an attempt to separate plutonium from spent uranium for the same purpose. The question is whether the building of a separation plant for fissile material is to be prohibited by the non-proliferation treaty, or whether the restrictions apply only to the production of that plant. And what will the treaty say about the natural uranium which is in any case the starting point ? The first point of view will expose the present nuclear powers to the charge that they are interfering unwarrantably in the affairs of others. The alternative, unfortunately, implies such detailed inspection of fissile material, not facilities, that this too may seem like unwarrantable intrusion. But a treaty on non-proliferation would be well worth having, which implies that the nuclear powers should not lose patience if they have to spend a year or more

at Geneva on this round of talks. They should also not be afraid of accepting some of the restraints they would impose on others.

## HOME FOR ARCHITECTS

THE Architectural Association in London is a most distinguished institution, with a long history of daring and innovation in the training of architects. It is also remarkable among British academic institutions in that it provides full-time courses for four hundred students or so without being a part of a university. To be sure, its qualifications count as if they were academic degrees, so that successful students are able to mix on equal terms with those from other architectural schools. (Indeed, given the great reputation of the association, they are sometimes thought to have an advantage.) But if academic standards are not a problem, survival is. In recent years the Architectural Association has found it increasingly difficult to keep going when its income is substantially no greater than the fees its students pay. Even though it has been possible to extract from them tuition fees of some hundreds of pounds—several times what students pay for tuition at British universities—the income from each student has been much less than the average cost per head of students at ordinary universities—something like £750 per head per year. No wonder, then, that the association must rub along with inadequate premises, and by paying its teachers less than the going rate so that it lies halfway between an academic institution and a kind of charity. No wonder, too, that the association has been looking for some place in the university system where its identity could be preserved but its exposure to the harsh winds of economic reality cushioned by the University Grants Committee.

Considerations like these have led the association to think of a marriage with the Imperial College of Science and Technology, and this by all accounts would be welcomed by the larger partner. The University Grants Committee is also, apparently, well disposed towards the match but not yet in a position to put its hand in its pocket and agree to add the Architectural Association to the payroll of the college. This is why a group of distinguished architects has now complained in public that the University Grants Committee must do something quickly, or the association will collapse before the marriage can be arranged. If this helps the University of London, Imperial College and the University Grants Committee to resolve their difficulties, it will be a useful step. But there are other problems to be tackled. If the Architectural Association is to be as valuable within Imperial College as it has been outside, it will need a handsome dowry—at least enough to build itself a building and to keep its traditional informal links with practising architects who serve as teachers. Ironically, of course, such a dowry would help to take the edge off present anxieties about the immediate future. The architects who have now complained should follow their protest

with an attempt to collect the sum of money which the association needs, one way or the other.

## TECHNOLOGY ON TOP

ON February 15 the Ministry of Aviation was formally merged with the Ministry of Technology, and the government department which the ministry itself has been calling "Mintech" became one of the largest, and potentially one of the most influential, in the British Government. Things have changed a lot in the two years since people were wondering just what the ministry had been created for—and how long it could last. The way in which the ministry has accumulated new responsibilities is in itself a kind of guarantee of survival. It is too important to be allowed to fail. But in the past six months the ministry seems also to have worked out for itself a framework within which it can function usefully and even imaginatively. Some of the unrealistic ambitions which were hung like albatrosses round the neck of the ministry when it was first set up have now been discarded. There is now much less to be heard, for example, of the "creation of new industries based on science". Instead, there is a much more realistic recognition that the immediate problem is to make all industries more productive. And there is much less talk of how it might be possible to make Britain less dependent on imports by deliberately developing substitutes. Instead, the ministry is turning out to be a source of encouragement to those who export—and a scourge to those who do not. No doubt the newcomers to the ministry—officials as well as ministers—have helped to make pragmatism respectable, but the ministry has also learned some useful lessons the hard way.

It does not follow that everything will now be plain sailing. It will be a long time, for example, before the old aviation research and development establishments can be welded into the structure of their new ministry and also given useful jobs to do. Many of the establishments have outgrown the problems with whose solution they were originally concerned, but attempts to make them more useful by turning them into free-lance research and development agencies for industry have not been successful. It would be far better if the ministry could find some way of placing some parts of its new empire in other environments. A deliberate dispersal of talent in commerce and industry is something real to aim at. Then the establishments should also be persuaded that it is no part of their business to build up a strong line in academic research, even if that does help in recruiting. Much better to form strong links with universities. And in the long run, the ministry should aim to use its establishments not as an independent machine for research and development but as a superior kind of management consultancy, able to turn its attention quickly to where it can be most useful. For even with its new strength, the ministry cannot hope to do everything by itself.

## NEWS AND VIEWS

### Loaves from Fishes

AFTER long hesitation, the United States Food and Drug Administration (FDA) has given its blessing to the protein concentrate with the unpalatable nickname of fish flour. Since 1961, congressmen from seafaring states have prayed for this event, sometimes gulping handfuls of fish flour in front of colleagues to prove that it is edible and does not taste of fish. But the FDA twice refused to rule the product safe, and thereby to open the way for its export to populations elsewhere starved of protein, because fish flour is made from the whole fish—entrails, stomach contents and all. To the FDA, this constituted filth—unacceptable in American food, and, by extension, in food shipped to poorer countries.

A little more than a year ago, however, a committee of the National Academy of Sciences turned the tide in favour of fish flour, declaring it to be not only safe but nutritionally valuable. The Bureau of Commercial Fisheries had meanwhile been busy at its laboratories in Beltsville, Maryland, trying to eliminate residues of the manufacturing process to which the FDA objected. (The bureau has found that isopropyl alcohol is satisfactory for extracting oil and water from the fish while keeping it palatable and stable.) And Congress became converted; last November it authorized a programme of research into fish protein concentrate—provided that the FDA gave its approval. That the agency has now done, just after President Johnson put a request for \$1.7 million for experimental FPC plants in his new budget.

True believers in FPC claim that it is the answer to protein deficient diets the world over. The product can be mixed with flour to make bread, noodles, cake or soup, or it can simply be sprinkled, as a protein additive, on food already prepared. It seems to offend neither taste nor taboo. And it is cheap—about 15 cents a pound for a substance which is 80 per cent protein. To make it, the Americans use hake, a fish rejected by their fishermen as a “trash fish”. The Fisheries Bureau estimates that about 12 billion pounds of this fish a year could be harvested, enough to supplement the diets of  $10^9$  people for 300 days at a cost of less than half a cent a day each. Once the manufacturing process has been refined, it seems likely that FPC could be made at many places around the globe—Sweden, Thailand and Morocco already produce it—and from other species than hake.

In the United States, FPC will be sold to begin with in packets of one pound or less; manufacturers are not to use it without giving evidence to the FDA that they are not deceiving the consumer. It must also be labelled with the advice that children under eight should not be given more than 20 grams a day, to guard against the mottling of their teeth from fluorides. This possibility will also be lessened by the insistence of the FDA that part of the fish bone be removed in processing to reduce fluoride residues.

### Artificial Kidneys

THE development of artificial kidney machines in Britain will not be accelerated by private donations or by an increased level of public spending. This at least is the verdict of the Ministry of Health, conveyed in a statement in the House of Commons by the Minister, Mr. Kenneth Robinson, on February 8. According to Mr. Robinson, there are three factors holding up development; the need to train staff, the time taken to plan and build accommodation for the units, and the risk of infection. At present, Mr. Robinson said, 116 patients are being treated in hospitals or at home, and the intention is to establish up to 20 main centres, each capable of treating 25 to 30 patients on twice weekly dialysis. There were, he thought, between 1,500 and 2,000 people who could be treated by renal dialysis; presumably the ministry is hoping that the difference between the number wanting treatment and the number of places available will be filled by those treating themselves at home.

The most serious factor is the risk of disease. The disease transmitted by the treatment seems to be serum hepatitis, a viral infection endemic in any part of the world. Patients with renal failure are likely to suffer because their disease involves them in a large number of blood transfusions; the Blood Transfusion Service refuses blood from donors who have had jaundice, but it is probable that there are a number of donors who have had sub-clinical attacks of serum hepatitis which were not diagnosed. The disease is spread from biological fluid to biological fluid, and can therefore be transmitted if a patient's blood is spilled on to abrasions on the hands of doctors and nurses; this may explain the serious outbreaks of jaundice at two renal dialysis units, at Manchester and Liverpool. Doctors regard the hazards as considerable, and are firmly resisting the pressure from the Ministry of Health to increase their work load.

Fortunately, the dangers to the health of the staff of renal dialysis units make home treatment even more attractive, or so some doctors believe. Dr. F. M. Parsons of the Renal Research Unit at Leeds believes that treatment at home may be better because fewer people are involved with the machines, and are likely to look after them better. Home treatment, of course, presupposes that the patient has the right sort of home, with a room that can be set aside for the purpose, and that the patient has some intelligence, and co-operation from his family. It is no quick and easy solution, however; patients require three months full time training in hospital to learn to use the machines.

### Reform at Oxford

THE University of Oxford shows signs of edging gingerly towards reforms recommended by the Commission of Inquiry under Lord Franks. On February 14, new statutes were read before Congregation which would alter the status both of Convocation and of Congregation itself. A debate on the new statutes will follow in two weeks.

The university is run by three bodies. Congregation, the supreme power, consists of almost everyone in a responsible position—the Chancellor, Vice-Chancellor,

Proctors, members of the faculties, members of committees, heads of colleges, and the like—and approves all legislation. The Hebdomadal Council looks after the running of the university, and consists at the moment of five ex-officio members and eighteen members elected by Congregation; it can submit legislation to Congregation. Convocation consists of all graduates of the university who hold a Master of Arts or higher degree; membership is therefore automatic to all graduates of the university if they apply for their Master's degree which is awarded after payment but without examination to all B.A.s 7 years after their matriculation. It is the powers of Convocation which will be most affected if the new statutes are passed; the power to elect the Professor of Poetry and the Public Orator, among others, will pass to Congregation, a loss which Fleet Street will probably feel more keenly than the university. Convocation will also lose the power to debate legislation which has not gained a two-thirds majority in Congregation, and will retain only the power to elect the Chancellor of the university by postal ballot. New statutes covering the Hebdomadal Council have also been published, and will be debated in the next few weeks.

The changes, if they are approved, will not greatly affect the administration of the university; in fact they give the impression of tinkering with inessentials while the need for a major overhaul is ignored. Those who feel that the stoutest defence of academic freedom in Oxford is provided by the general obscurity of the university's administration need feel no alarm about the new statutes. Two former Professors of Poetry have declared their opposition to the proposals. If this feeling is shared by more than one-third of Congregation, then presumably the new statutes will pass to Convocation for approval. Convocation will then have to give its opinion of proposals calculated to make its opinions irrelevant, a situation of some constitutional nicety.

## Scientific Advice

THE Scientific Branch of the Greater London Council advises the council on matters in which scientific judgment is valuable. The report of the Scientific Adviser for 1965 (G.L.C., 5s.) gives details of this work, and of the Scientific Branch, which has been divided into four main groups: Research and Materials, Analytical, Sewage Treatment, and Technical Support.

The Thames seems to be less polluted than in the past; the dangerous situation arising when there is no dissolved oxygen in the water has occurred less frequently. The air also seems to be fresher, with the sulphur dioxide content down by 14 per cent and the concentration of smoke down by 23 per cent. Clean fuels and efficient heating appliances have caused this encouraging improvement; there were no seriously polluted fogs during 1965. The branch has also been concerned with the examination of building materials, both as a means of quality control and to trace and eliminate defects; it is interested in replacing expensive materials with cheaper ones wherever possible. In addition, it has carried out the responsibilities of public analyst, ranging from dirty milk bottles (a common complaint) to the amount of meat in meat pies. Standards proposed for meat pies but not yet in force would require 25 per cent total meat, not on

the face of it an impossible requirement; pies with less than 25 per cent meat are to be described as cornish pasty.

## Feeding the 500 Million

It is difficult to say anything new about the problems of feeding the underdeveloped countries. *Science Reporter*, an Indian scientific journal published by the Council for Scientific and Industrial Research at New Delhi, has bravely devoted the whole of its latest issue to the problem. The magazine includes contributions from a number of distinguished men, including United States Secretary of Agriculture Mr. Orville Freeman, and United Kingdom Minister of Agriculture Mr. Frederick Peart, who briskly run through their respective paces without saying anything unexpected. Mr. Freeman believes that the war against hunger can be won, and details the amount of aid the United States has provided since 1954 (150 million tons of food, worth \$15.10<sup>9</sup>), while Mr. Peart applauds the growth rate of agriculture in Britain (6 per cent per year from 1960 to 1964) without saying how India can hope to do the same.

Perhaps the time for generalities is past, in any case. The contributors become more interesting as they become more specific. India has more than 4,600 km of coastline and one-fifth of the cattle in the world, but produces only 2.5 kg of fish per person per year, one of the lowest totals in the world, and only one cup of milk per person per day. Population control, the contributors agree, is essential; Dr. V. G. Panse of the Planning Commission in New Delhi believes that without it there is no chance of the Indian population reaching even the minimum nutritional level in the next 50 years. It also seems agreed that none of the present contraceptive methods is ideal; the loop is spreading, but if, as one writer suggests, its success depends on insertion by "trained lady doctors", progress is likely to be imperceptible. In 1961 there were about 4,200 trained lady doctors in India, for a population which has just passed 500 million. Perhaps the most hopeful avenue is the prevention of waste; Dr. S. V. Pingale of the Ministry of Food in New Delhi estimates that no less than 10 per cent of the grain in India is lost through indifferent handling and the depredations of insects and rats.

## John Doe, Scientist

THE National Register of Scientific Personnel, operated jointly by the National Science Foundation and the principal learned societies, has now been made to yield a detailed profile of the life and work of the scientific population in the United States (*American Science Manpower 1964*, Government Printing Office, \$1.25). In 1964, it seems, the median age of scientists on the register was 38, and 35 per cent of them had doctorates. 60 per cent of those on the books worked in the physical sciences, with life sciences claiming 24 per cent and other disciplines (including mathematics and some social sciences) the rest. Of all scientists, 38 per cent worked in industry and nearly as many—32 per cent—in educational institutions of all kinds, schools as well as universities. In practice, only just over a half of those employed in education are actually teachers: in 1964, 18 per cent of those on the register confessed

to teaching as their principal activity. Research and development occupied 35 per cent of all scientists, while administration and various managerial activities took 21 per cent.

The details of salary will probably command the closest attention—not only among those about to emigrate to the United States. In 1964 the median salary for scientists in the United States worked out at \$11,000, but there were significant variations from discipline to discipline, age to age, and even from place to place. The median salaries of economists, physicists and statisticians were \$1,000 above par. Chemists and mathematicians had median salaries of \$11,000, but other disciplines fell below par with agricultural scientists near the bottom of the list with median salaries of \$9,200. The possession of a Ph.D. degree seems to confer an advantage of \$2,000 in salary—the difference between the median salary of \$12,000 for doctors and \$10,000 for those with master and bachelor degrees. It is plain that the management and administration of research and development is more rewarding (median salary \$15,500) than research and development itself (median \$11,000), although this comparison is in part vitiated by the predominance of scientists with doctorates among the administrators. The median salary in industry or commerce worked out at \$12,000. The corresponding figure for educational institutions was \$9,600—a figure calculated on the basis of an academic year of nine or ten months for a good many teachers.

For all scientists, the upper and lower quartiles of the salary distribution lie at \$14,000 and \$8,600. Predictably, there is more uniformity among the lower quartile salaries earned in different specialities than among the upper quartiles, which range from \$11,200 (for agricultural scientists) to \$16,000 for economists. Economists are among the most highly paid of the scientists and social scientists on the national register, and 10 per cent of them earned more than \$20,000 in 1964. Among the pure scientists, straightforward biologists seem to have done slightly better than physicists and mathematicians, with an upper decile of \$19,000 (compared with \$18,700 for physics and \$18,500 for mathematics). Women, who account for 7.6 per cent of the scientists on the register, earn less than men. Their median salary works out at \$8,400, with the greatest rewards in the social sciences. Undoubtedly a part of this apparently unflattering comparison is to be explained by differences of age distribution and even of qualification between the sexes. Salaries increase with age up to the late fifties, with a median of \$7,000 between 20 and 24 and a plateau of about \$13,000 or just above which seems to be reached in the late forties.

## Mintech Marriage

THE Ministry of Aviation was formally merged within the Ministry of Technology on February 21, after some hectic days in the House of Commons when it seemed as if the enabling legislation would be defeated by procedural difficulties. In the new ministry Sir Richard Clarke will remain the administrative head. Sir Richard Melville, hitherto Permanent Secretary at the Ministry of Aviation, will become head of the Aviation Group. The direction of the scientific

establishments is to be shared between Dr. George MacFarlane and Mr. Ieuan Maddock. Dr. MacFarlane, at present director of the Royal Radar Establishment, will become Controller (research) with responsibility for the research stations already within the ministry, the Atomic Energy Authority, the National Research Development Corporation, the research associations and, eventually, the research establishments transferred from aviation. Mr. Maddock will be Controller (industrial technology), and will be responsible for the work of the ministry in promoting development within the engineering industry.

## Jobs for Biologists

BRITISH biologists who are looking for jobs will take heart from the results of a survey carried out by the Institute of Biology (*A Survey of the Employment of Graduates in Biological Posts in the United Kingdom: J. Inst. Biol.*, **13**, 131; 1966). The survey made use of published information on the specialization of biologists in the Civil Service, government research and education, and detailed questionnaires were sent to companies to obtain information about biologists in industry. The survey should put an end to the myth that biology graduates have poor prospects of employment. Of the eleven thousand graduate biologists employed in the principal British centres, nearly five thousand are teachers, chiefly in secondary schools. Another five thousand are about equally divided between state aided research and the universities, and the remaining fifteen hundred are employed in industry. There are 1,085 biochemists, 868 microbiologists, and 797 animal physiologists—the 4,143 general biologists are almost all engaged in teaching.

The form of the survey made it possible for the institute to estimate the rate of growth of the demand for biology graduates. Certain specialities, such as microbiology and toxicology, seem to be inadequately supplied with qualified people. The demand from industry so much exceeds the supply of such graduates that the additional requirement by June 1967 will be 25 per cent of the existing number of industrial microbiologists. Many of the available posts in such specialities are, of course, filled by scientists from related disciplines, but companies often find that it is expensive to retrain such people. The institute thinks there is a case for more specialized courses at the undergraduate level in subjects like industrial microbiology, and for establishing new departments where these do not already exist. Such a solution would solve the immediate problems for industry, but it would be at the expense of any attempts there might be to broaden the horizon of biology teaching in the universities. The proper place for specialized teaching of this sort is at the graduate level, and it is encouraging to see that many universities are now starting all their biology students on a general biology course.

Industry expects a rate of growth in the demand for biologists of 10–15 per cent each year. The universities are working on the assumption that they will require about 7 per cent more biology graduates each year. Applied biologists should benefit most from this labour shortage, but university and research biologists will also be assured of a place.

## Maps by Order

THE surveying and mapping of the British Isles are carried out by the Ordnance Survey. Despite an air of brisk efficiency, aided by a preponderance of army officers in senior positions, the survey has recently been the victim of some distinctly undisciplined shuffling in Whitehall. After 75 years in the care of the Ministry of Agriculture, the survey moved in 1965 to the Ministry of Land and Natural Resources, but had barely drawn breath before that ministry went into eclipse—it is at present in the process of dissolution. The survey now has its third Minister in two years—the Minister of Housing and Local Government, Mr. Anthony Greenwood.

The survey's work does not seem to have been disturbed by this uncertainty. It is still a long way from completing the basic survey of Great Britain, but is making progress. Three basic scales are used; 1 : 1,250, 1 : 2,500 and 1 : 10,560 (6 in. to 1 mile). So far, however, maps of the whole country are available only at scales of 1 in. to 1 mile (1 : 63,360) and 0.25 in. to 1 mile (1 : 250,000). Most urban areas are now mapped at scales of 1 : 1,250, but there is still much to do before the 1 : 2,500 plans of the counties are completed. Maps of mountains and moorland areas are also to be published, at the 1 : 10,560 scale, but here there is an enormous amount of work yet to be done. Another series has been undertaken during the past year, at 2.5 in. to 1 mile, and various archaeological and tourist maps are also available.

The survey is now more optimistic about finishing its task by 1980. During his tenure of office, Mr. Fred Willey, Minister of Land and Natural Resources, authorized a 20 per cent increase in the staff of the survey over 10 years. Without this, reports the Director-General of the survey, Major-General Edge, in the annual report for 1965-66 (H.M.S.O., 7s. 6d.), the job would hardly have been finished before the end of the century. Operations should also be easier when the survey moves to new headquarters in Southampton; this will bring together the work carried out in Esher and Chessington in Surrey and the drawing and reproduction department in Southampton.

If the move makes the work of the survey any less expensive, nobody will complain, as the budget is hardly chickenfeed. Expenditure last year was £5.5 million, against receipts of £1.7 million. The survey has a staff of 4,548, with 1,718 surveyors and 1,274 draughtsmen. The impression of a military machine is perhaps deceptive, as there are only 26 army officers on the staff, but most of them seem to be concentrated in the top executive positions.

## Qualified Success

THE fourth French earth satellite launched from North Africa on Wednesday, February 8, and known as *Diademe*, seems to have been only a partial success. The device, of mass about 15 kg, was found after launching to be in an orbit about the Earth with an apogee substantially lower (1,340 km) than that planned (1,843 km). It is therefore possible that the geodetic triangulation measurements which had been planned will now be difficult and even perhaps impossible. The original orbit was chosen so that the satellite would be simultaneously visible from three ground stations around the Mediterranean—at Colomb-Bechar

in the Sahara, Saint Michele-de-Provence in France and at a station on the Gulf of Corinth. Lasers at each of the stations, together with Doppler measurements, were to have been used for triangulation. No doubt it will be possible to make good use of observations from pairs of stations and also from sky photography from several observatories beneath the orbit, but some precision will undoubtedly be lost.

Those responsible for the rocket programme were hoping earlier this week to repeat the triangulation experiments by launching a second satellite (and the fourth in the present series) into a somewhat higher orbit. The launching was due to take place on February 15.

## Do Worms Learn?

THE controversy about the mechanism by which planarian worms appear to learn by the ingestion of nucleic acids from other worms remains unresolved despite the deliberations of a conference at Michigan State University, East Lansing, last year (1966). Several papers at the conference were devoted to the factors which may directly or indirectly affect the results observed. There appear to be marked differences between the properties of planarian worms of different species—and there are as many as forty species in the United States. Much of the evidence which supports the notion of a chemical basis of learning has been based on experiments which demonstrate that an acquired response can survive regeneration, and a French participant at the conference described how different species of planaria differ in a mechanism of tissue renewal. Some do not regenerate at all. Others regenerate only at the front and others regenerate at any point along the axis. This obviously affects the way in which acquired information can be retained during regeneration. Among other animals to which the chemical basis of learning may be important are what have been described as the "micrometazoa"—hydra and so on. The conference also heard of experiments with the isolated insect ganglion, and one participant produced evidence which indicates that a single isolated ganglion in a cockroach can acquire an avoidance response. There is also histochemical evidence that may enable identification of the muscles and axons that are involved in information storage.

## Control of Haemoglobin Function

from a correspondent in Molecular Biology

ONE of the most tantalizing problems in molecular biology concerns the nature of the haem-haem interactions in haemoglobin. It is well established that a conformational change occurs during oxygenation, but in spite of the detail in which the structure—at least of the oxygenated form—is known, how the change is controlled and transmitted remains obscure. The problem has the widest relevance to control mechanisms in enzyme systems.

Among the more promising approaches have been attempts to block selectively the coupling between the haems and the Bohr effect. Thus it has been found that normal human haemoglobin can under some circumstances be made to remain in the same confor-

mational state throughout the oxygenation reaction. This is the state of high affinity for oxygen, which physiologically is responsible for the high reactivity of the fourth haem after the other three have reacted: the rate of combination with oxygen in this step is known to be some forty times greater than in the earlier phase. It has been found that only the high-affinity state is observed in haemoglobin H, the abnormal human form which contains  $\beta$  but no  $\alpha$ -chains, in haemoglobin pre-treated with carboxypeptidase (which selectively removes residues from the C-termini), in isolated  $\alpha$  and  $\beta$ -chains and in a form of haemoglobins produced by photolytic removal of ligands in which the conformational change does not have time to occur. Another case was discovered recently, when it was observed that no haem-haem coupling (or Bohr effect) is present in haemoglobin complexed with haptoglobin, a specific haemoglobin scavenging plasma protein.

The initial observation has now been extended by Nagel and Gibson (*J. Mol. Biol.*, **22**, 249; 1966), who have measured the velocity of carbon monoxide binding to haemoglobin in such a complex. First, it is found that the velocity does not depend on  $pH$ —there is no Bohr effect; second, the rate for the complex is an order of magnitude greater than for free haemoglobin. In flash photolysis experiments, moreover, it is noted that, unlike free haemoglobin, the complex shows no biphasic rate curve, and the absence of haem-haem coupling is clearly inferred. There is also a markedly lower activation energy for the process in the complex. It therefore appears that haptoglobin associates with haemoglobin in its high-affinity form, and locks its conformation in that state. The experiments have been performed with two genetically different haptoglobins, one of which is in a higher polymerization state. Qualitatively, the complexes behave similarly in respect of carbon monoxide binding, but differ considerably in rate constants and activation energies.

A most remarkable observation on the regulation of haemoglobin function has been made by the Benesch (*Biochem. Biophys. Res. Commun.*, **26**, 162; 1967), and this will without doubt re-direct much of the current thinking in the field. The authors set out from the fifty-year-old observation that, in the absence of particulate salts, haemoglobin loses its sigmoid oxygen dissociation curve and behaves like myoglobin. Its oxygen affinity is then very high. Although this curve is not affected by sodium chloride or sulphate, the phosphate ion is shown to decrease oxygen affinity and to generate a perceptible haem-haem interaction. On the other hand, the compound 2,3-diphosphoglyceric acid, which exists in substantial concentration in the mammalian red cell, produces at millimolar concentrations a dramatic shift in the oxygen dissociation curve to precisely the position associated with a normal haemolysate or whole blood. Indeed, when the oxygen affinity or the exponent  $n$ , which measures the degree of haem-haem interaction, is determined as a function of diphosphoglyceric acid concentration, there is a very sharp rise and, particularly in the case of  $n$ , no further change with a more than tenfold increase in concentration. This suggests the presence in haemoglobin of specific binding sites of high affinity for diphosphoglyceric acid and its analogues (a number of which have also been studied), and indicates that it is this ligand which determines the allosteric properties of the protein.

## Parliament in Britain

IN a written answer in the House of Commons on February 13, the Secretary of State for Education and Science, Mr. A. Crosland, announced that the Government intended to set up a special fund which would enable grants to be made to students from overseas if they could show that the recent increase in tuition fees would involve them in hardship. The aim was to ensure that overseas students already here would not be prevented from finishing their courses because of hardship. It was too soon to give details of these arrangements, but the long term situation would be kept under review by the departments concerned.

IN a written answer on February 3, Mr. Crosland stated that in 1955–56 there were 9,290 overseas students at full-time and sandwich courses in universities, the estimated subsidy being £3.4 million; the figures for further education establishments were not known. In 1961–62 the corresponding figures were 13,020 and £6.9 million for universities and 13,770 and £3.2 million for further education establishments; and for 1965–66, 16,256 and £12.0 million, and 16,292 and £6 million, respectively. The subsidy in 1967–68 under the new arrangements was expected to be no less than in 1965–66.

IN a written reply to a question in the House of Commons on February 9 regarding research in Government establishments into fishermen's diseases during the past five years, the Minister of State, Department of Education and Science, Mr. G. Roberts, stated that a study was being made in the Department of Social Medicine, University of Aberdeen, of causes of death among a group of trawlermen.

IN reply for the Government on February 3 in an adjournment debate in the House of Commons on sonic boom problems in civil aviation, the Minister of Aviation, Mr. J. Stonehouse, agreed that it was important to have a proper evaluation of the position regarding the sonic boom as supersonic transport developed. Apart from the possibility of damage to structurally unsound buildings, he thought there was no real likelihood of damage or loss being caused on the ground as a result of sonic bangs such as were likely to be caused by the Concord aircraft. Mr. Stonehouse pointed out that it was also necessary to consider the economic viability of the Concord project if supersonic flight over land was disallowed. A complete ban on supersonic flights over land would reduce the market for the Concord to 55–65 per cent of that at present expected and to 75 per cent if the ban was partial.

REPLYING for the Government on February 6 in an adjournment debate in the House of Commons on the oil pollution of beaches, the joint parliamentary secretary to the Ministry of Housing and Local Government, Mr. J. MacColl, emphasized that dispersal at sea was not a Government responsibility: that responsibility was limited to detecting offenders and trying to bring them to book. The Warren Spring Laboratory had studied techniques for removing oil from beaches, including full-scale trials at Shoeburyness and Eastbourne, and a technical working group to find an efficient and economic method of combating oil pollution on beaches started work in October 1966.

## University News:

London

PROFESSOR J. LEWIS, professor of inorganic chemistry in the University of Manchester, has been appointed to the chair of chemistry tenable at University College, and Professor O. J. Lewis, professor of mammalian morphology at St. Bartholomew's Hospital Medical College, has been appointed to the chair of anatomy tenable at that college.

## Strathclyde

A DEPARTMENT of Computer Science has been created and an extensive programme of development in computer work, centred on a newly installed ICT 1905 machine with a 32K word core store and magnetic tapes, has been launched by the university. It is hoped that an undergraduate degree course in computer science will soon be introduced.

## Appointments

MR. R. B. ABEL, formerly assistant research co-ordinator, Office of Naval Research and executive secretary of the Interagency Committee on Oceanography, has been appointed head of the U.S. National Science Foundation's programme to implement the National Sea Grant College and Programme Act of 1966. The Act assigned to the foundation the task of mobilizing appropriate institutions to play a more significant part in the development of marine resources through education, research, and advisory services.

## Announcements

THE U.S. Atomic Energy Commission has appointed an advisory panel on high-energy physics to help foster "a vigorous and productive national high-energy physics programme". The chairman is Professor Victor F. Weisskopf of M.I.T. The panel includes Dr. Rodney L. Cool (Brookhaven National Laboratory), Professor Earle C. Fowler (Duke University), Professor Leon Lederaman (Columbia University), Dr. Edward J. Lofgren (Lawrence Radiation Laboratory), Dr. George E. Pake (Washington University), Professor W. K. F. Panofsky (Stanford University), Professor Robert G. Sachs (Argonne National Laboratory), Professor Keith R. Symon (University of Wisconsin), Professor Robert L. Walker (California Institute of Technology), Professor Robert R. Wilson (Cornell University) and Professor C. N. Yang (State University of New York).

A DELEGATION from the Royal Society, consisting of Professor H. W. Thompson, Dr. R. D. Keynes and Dr. D. C. Martin, is visiting Bulgaria during February 17-23 at the invitation of the Academy of Sciences of the People's Republic of Bulgaria. The purpose of the visit is to sign a direct agreement for scientific collaboration between the society and the Bulgarian Academy of Sciences.

THE Ford Foundation has made a grant of \$200,000 over a period of three years in support of the Royal Society's new European Programme, which is aimed at strengthening the European scientific community by promoting interchange between scientists. This grant will be used to support the European Programme of fellowships at postgraduate and postdoctoral levels, study visits of shorter duration and small European research conferences. The first closing date for applications for fellowships is February 28.

THE meeting of the Mass Spectroscopy Group on "Analysis of Inorganic Solids", which was to be held at the University of Manchester on April 5, has been cancelled.

**ERRATUM.** The statement on the Information Exchange Groups in *Nature* last week (213, 547; 1967) was wrongly attributed to the "Commission of Biological Editors". The statement was, in fact, prepared by the Commission of Editors of Biochemical Journals under the International Union of Biochemistry.

## CORRESPONDENCE

## Fire Risks in Space Capsules

SIR,—There are important weight and control system advantages to using a pure oxygen atmosphere for space vehicles. In such a system one purges the capsule with pure oxygen at a pressure slightly greater than atmospheric for some hours and then allows it to vent to a pressure of about 5.5 p.s.i. in the case of the "Apollo" and early MOL projects during the first minutes of lift-off and ascent. Thereafter the capsule atmosphere is maintained as pure oxygen at that pressure. During descent the environment of the crew is returned to atmospheric pressure by the inlet of air. During the purging procedure and in pressurized flight the crew breathe through the open visors of their pressure helmets.

The fire studies carried out at this institute some time ago suggested that a threshold existed for the appearance of flash fires in oxygen rich gas environments, and that this threshold was unlikely to be below 6.0 to 6.5 p.s.i. partial pressure of oxygen. It seems to us that this has important implications for the future of single gas space vehicle systems. If, as it suggests, the in-flight condition carries no risk of flash fire, one can think of two methods which eliminate that risk from the remainder of the flight envelope, and retain the advantage of single gas systems without structural or control system modifications. Both involve breathing, with the helmet visor closed, from a personal supply of pure oxygen until the respirable atmosphere of the final flight condition is achieved some minutes after lift-off.

The methods are: (a) Dilution of the cabin oxygen with a soluble gas which can be absorbed once the fire hazard has been removed by a fall in the total environmental pressure. (b) The use of a mixture of oxygen and an insoluble gas, which can later be voided to the external vacuum and replaced by pure oxygen.

Carbon dioxide would appear to be an obvious choice for the soluble gas, because absorbants are already required for removing the carbon dioxide produced by metabolism. It is estimated that an additional two pounds of lithium hydroxide would be needed for the cabin of a spacecraft with a volume of 150 cubic feet, an atmosphere consisting of 40 per cent of oxygen and 60 per cent of carbon dioxide and a total pressure of 6 p.s.i. A similar weight of oxygen (equivalent to the metabolic needs of one man for one day) would suffice to restore the atmosphere of the spacecraft to the desired pressure. Engineering problems associated with the control and handling of large quantities of carbon dioxide during the purging phase might, however, dictate the choice of some other soluble gas.

Air would be a satisfactory mixture for the second method, the major disadvantage of which is the necessity for a decompression of the capsule early in the flight. Five pounds of oxygen would be enough to replace the atmosphere of the cabin.

Clearly, these arguments hinge on the existence and level of a threshold for flash fires which we know to be somewhat dependent on the nature and history of the supporting surface. The present series of fire studies at this institute is intended to give a better understanding of this phenomenon. This threshold might be exceeded on re-entry until "splash-down".

Both the solutions require that the crew have their visors closed for some hours before orbital flight is attained. This appears to be a small price to pay.

Yours faithfully,

D. M. DENISON

# Fluorescence Microscopy with the Quartz-Iodine Lamp

by

M. R. YOUNG

J. A. ARMSTRONG

National Institute for Medical Research,  
Mill Hill, London, N.W.7

Many dyes fluoresce when they are irradiated with light of particular wavelengths. This is the basis of some specific microscopical staining techniques, especially in the field of immunology. Where activation depends on blue-violet light the quartz-iodine lamp is a useful and convenient source for fluorescence microscopy.

THE fluorescence microscope has developed from a specialized apparatus for research, where elaborate or inconvenient equipment may be acceptable, to the present stage when it is increasingly needed for routine use in biology and medicine. Convenience and simplicity of operation have become important considerations. Recently it was suggested that the cadmium lamp<sup>1</sup> is a feasible and highly efficient light source for immunofluorescence microscopy. The only cadmium source with adequate intrinsic intensity is the cadmium electrode spark; unfortunately this apparatus is expensive and inconvenient. It may therefore be useful at this time to report on experience gained in this laboratory with the quartz-iodine lamp, which merits consideration as a possible alternative to the mercury high-pressure lamps that have hitherto been regarded as the only adequate and practical light source for activation of fluorescence in microscopical specimens<sup>2</sup>; the carbon arc gives good results but is inconvenient in use.

Tungsten filament lamps as ordinarily used for light microscopy have occasionally been used for fluorescence microscopy<sup>3</sup>, but it is generally agreed that their efficiency is low. The ratio of useful blue-violet light to total energy output is diminished in practice by two factors: first, the proximity of the excited fluorescence to the activating maxima in the blue region necessitates the use of a primary filter with a sharp cut-off in transmission at 500 m $\mu$ ; second, there is an intense emission of visible light extending into the red region, which must be effectively absorbed by the primary filter. Inevitably the intensity of the required blue-violet emission falls below a useful level. If the lamp is over-run at high voltage it is possible to boost the output of useful blue-violet light; but the life of the lamp is then drastically reduced.

The 100 W quartz-iodine lamp is a very compact tungsten filament source, with a quartz bulb in which a small quantity of iodine is enclosed. The filament operates at a higher temperature than in conventional tungsten lamps, giving greater efficiency in the production of light. As a result of the "iodine cycle", in which evaporated tungsten redeposits on the filament, the quartz remains clear until burn-out. An important feature in relation to fluorescence activation is that the inclusion of iodine modifies to some extent the emission spectrum, by selective absorption in a broad band in the yellow-green region; violet emission below 430 m $\mu$  seems to be increased as the radiant energy from the filament passes through an atmosphere of iodine vapour<sup>4</sup>.

Compared with mercury lamps with an average life of 400 operating hours, the quartz-iodine source with 50 h appears to be at a disadvantage. In practice this is not necessarily so. Mercury-pressure lamps require a warming up period of several minutes or more before they reach full intensity, and also need to cool before the arc can again be switched on. Consequently many users leave the lamp burning for long periods even when it is

not actually in use. Quartz-iodine lamps can be switched on and off at will, and give full brightness at once. They withstand rapid voltage change, provided that the full wattage is not exceeded, and perform with only slight reduction in lumen efficiency when slightly under-run. Replacement costs are much less than for mercury-pressure lamps.

Comparison of the emission spectrum of the quartz-iodine lamp with that of mercury-pressure lamps shows that, whereas the latter emit light in the form of separated narrow bands or lines, with a strong line in the ultra-violet at 365 m $\mu$ , the quartz-iodine lamp gives a continuous spectrum (Fig. 1A). Ultra-violet output is negligible, but the intensity of the visible blue-violet emission compares well with that of mercury lamps<sup>2</sup>. Workers using the mercury-pressure lamp for fluorescence microscopy have often preferred to use the ultra-violet for the activation of fluorescein conjugates despite the fact that apart from a small peak at 325 m $\mu$  absorption by the

Fig. 1. A, Spectral emission curve for the Atlas 100 W quartz-iodine lamp, operated at 12 V; colour temperature 3,300° K (based on manufacturer's data). B, Spectral transmission curve for the Corning blue-violet glass filter No. 5850; thickness 4 mm.

dye between 300 m $\mu$  and 400 m $\mu$  is low<sup>5</sup>. A disadvantage of ultra-violet activation arises in some biological specimens, where the apple-green colour of specifically labelled areas may be modified or masked by autofluorescence of tissue components induced by ultra-violet light. Nairn<sup>6</sup> suggests that the strong absorption of fluorescein at 495 m $\mu$  is too close to its emission peak at 525 m $\mu$  for matched filters to function satisfactorily; because the blue-absorbing secondary filter cannot be exactly complementary to the primary filter, it may be difficult to distinguish between specific and non-specific coloration of the specimen. This is so if the specimen is to be illuminated with a bright field condenser; however, dark field condensers are now frequently used for fluorescence microscopy, and under these conditions a balanced filter system for blue-violet activation of fluorescein conjugates is readily made for any of the available light sources. It is frequently convenient, of course, if the secondary filter transmits a faint blue dark field image of the unstained elements of the tissue, facilitating localization of the specific fluorescence.

In view of these factors it is reasonable to expect the quartz-iodine lamp to function as a useful activating source, not only for work with fluorochrome dyes such as acridine orange, thioflavine, primulin or auramine, but also for immuno-fluorescent staining with fluorescein or rhodamine conjugates. Tests with a variety of biological specimens have been made in this laboratory to compare the performance of fluorescence microscope units incorporating the MED/250 high-pressure mercury lamp or the 100 W quartz-iodine lamp. The former was used in the horizontal optical bench apparatus previously described<sup>2</sup>; the quartz-iodine lamp formed part of a commercial fluorescence microscope (manufactured by Gillett and Sibert, Ltd.). The same type of cardioid dark-field condenser was used in each case. The primary filter in both was a Corning C.S. 7/59 No. 5850 blue-violet glass filter combination (see Fig. 1B); the secondary filter was an Ilford No. 107 gelatine film. Heat and red light from the quartz-iodine lamp were absorbed with a Chance ON.13 glass filter, and from the mercury lamp with a 10 per cent solution of cupric sulphate in a 1 cm thick cell. In one test, monolayer cultures of monkey kidney cells were inoculated with a B strain (Lee) of influenza virus and examined 24 h and 48 h later, together with control cultures, for the presence of viral antigenic materials. For immunofluorescent staining the cells were

fixed in alcohol and stored at  $-70^{\circ}\text{C}$ ; after treatment with guinea-pig antisera to the "S" or "V" viral antigens, they were stained with fluorescein-labelled rabbit anti-guinea-pig gamma-globulin serum. Changes in the pattern of intracellular nucleic acids were shown, after fixation in alcohol, by staining with acridine orange at pH 3.5. Newly formed virus at the cell surfaces, and the intranuclear localization of viral soluble ("S") antigen with its associated RNA, were observed with about equal clarity on the two microscopes. Photographic exposures indicated slightly higher intensity of fluorescence with the mercury lamp, but image contrast against the black background was better in the microscope fitted with a quartz-iodine source.

Our observations on these and other specimens indicate that when combined with a filter system properly matched to its emission spectrum, and provided that blue-violet activation is acceptable, the 100 W quartz-iodine lamp is a reasonable alternative to the mercury pressure lamp for general work on cell cultures or thin tissue sections. At the same time, more searching tests to compare the limits of sensitivity obtainable with different light sources may well show the mercury lamp to be superior. There are also cases where ultra-violet activation is essential; for example, in observations of autofluorescence from tissue components such as vitamin A, or for tracing reagents which absorb strongly only in the ultra-violet. Moreover, there are circumstances where the physical state of the specimens may preclude the use of blue-violet light; should the thickness or refractivity of the material exceed practical limits imposed by the method of dark-field illumination, for example in thick smears, excessive scatter of blue light may result and cause marked loss of contrast and definition in the fluorescent image.

It appears, in conclusion, that the quartz-iodine lamp in its present form has definite limitations, but is an adequate and very convenient light source for many biological applications of fluorescence microscopy.

We thank Atlas Lighting, Ltd., for permission to publish the technical information which they kindly supplied on the 100 W quartz-iodine lamp.

Genetics and Biophysics,  
Naples, Italy

Some living cells without their nuclei can continue to survive and develop, at least for a time. Do they use up stores of messenger RNA? Or are the organelles of the cytoplasm less passive than is often thought?

In recent years our embryological research has been directed towards a deeper understanding of the relationships during morphogenesis between the activities within the nucleus and those in the cytoplasm. The most suitable biological material for these investigations has been found to be the giant unicellular alga *Acetabularia mediterranea* and the eggs of the sea-urchins and amphibians. With each of these, it is possible to separate nucleate and anucleate cellular fragments. What follows describes

some of the findings which have emerged from our investigations.

### *Acetabularia mediterranea*

*Acetabularia mediterranea* (Fig. 1) measures 2–3 cm in length and can thus easily be cut into two parts, one containing the nucleus (which is located in the rhizoid), the other lacking it (compare Hämmerling<sup>1</sup>). Anucleate fragments can survive for several months, and can even

regenerate a reproductive organ—the cap. Except for its smaller size, the morphological aspect of the cap is typical of the species to which the nucleus belongs. This clearly implies gene expression in the absence of the nucleus. Analysis of interspecific nucleate and anucleate fragments of *Acetabularia* led Hämmerling<sup>2</sup> to the conclusion that the nucleus must produce "morphogenetic substances" which are specific to the species. Synthesized in the nucleus, they would migrate to the tip of the stalk and autonomously control the formation of the cap (Fig. 2).

We have been able to show<sup>3</sup> that net protein synthesis occurs in anucleate fragments. Within 3 weeks of nuclear ablation, the protein content increases by a factor of three. The proteins synthesized by the anucleate fragments include several enzymes the synthesis of which is usually considered to be controlled by genetic material—nuclear DNA.

The five isozymes of acid phosphatase are among the best known<sup>4,5</sup>. Their activity seems to be independently controlled even in anucleate cytoplasm. Two of them, which are associated with the chloroplast fraction, increase in activity when caps are formed by anucleate fragments. The activity of a third isozyme, not found in the chloroplasts, decreases with time.

Net synthesis of RNA can also occur in anucleate fragments, especially if the alga has previously been cultivated in the dark<sup>6</sup>. We have observed a two-fold increase in the RNA content of anucleate fragments over a period of 5–7 days. Earlier experiments by Naora *et al.*<sup>7</sup> have shown that this RNA synthesis primarily occurs in the chloroplasts.

When these facts are re-examined in the light of present knowledge, it seems probable that the morphogenetic substances are messenger RNAs which are stable and long-living. They would migrate from the site of synthesis on chromosomal DNA to the apex of the alga, and bring with them the information required for species specific cap formation. The duration of their life can be calculated from the length of time during which anucleate fragments maintain their capacity to form caps and synthesize proteins—about 2–3 weeks. Fig. 3 summarizes these ideas<sup>8</sup>.

Fig. 1. Vegetative development of *Acetabularia*, diagrammatic. c, Cap; ci, corona inferior; cs, corona superior; hw, hair whorl; n, nucleus; st, stalk; rh, rhizoid.

There is a great deal of evidence to support this hypothesis. Just as in other cells, nuclear (and particularly nucleolar) RNA is labelled first after a pulse of several hours with uridine. When the algae are later transferred to unlabelled seawater, the previously labelled nuclear RNA migrates towards the apex of the stalk<sup>9</sup>. Certain proteins which are also synthesized in the nucleus accompany the migrating RNA<sup>10,11</sup>. Werz<sup>12</sup> has also shown by cytological techniques that RNA and basic proteins collect at the apex of the stalk. Our explanation also accounts for what happens when pre-existing RNA is broken down, or when the DNA dependent synthesis of RNA is inhibited. Anucleate fragments treated with RNase<sup>13</sup> or by ultra-violet light<sup>10</sup> entirely lose their ability to regenerate and to produce caps, because the stable mRNAs which have accumulated in their tips are degraded and cannot be replaced in the absence of the nucleus. Nucleate fragments, on the other hand, are capable of replacing the degraded RNA by renewed syntheses, shortly after the RNase is removed or the treatment with ultra-violet light stopped; but if the synthesis of RNA is blocked by actinomycin, only the regeneration of the nuclear fragments is inhibited; the anucleate fragments are able to begin cap formation in a normal manner, because they already contain the required stable mRNAs. The formation of the cap is, however, slow and imperfect<sup>14,15</sup>. Puromycin and cycloheximide, which block protein synthesis, prevent regeneration in both nucleate and anucleate fragments, reversibly in the former, irreversibly in the latter (Brachet, unpublished). When regeneration occurs in nucleate fragments it is often abnormal and results in bifid or trifid stalks. An ordered synthesis of proteins is thus required for the formation of a cap<sup>14</sup>.

The fact that the formation of the cap is imperfect in anucleate fragments treated with actinomycin despite normal initiation may indicate that the antibiotic combines with the DNA of the chloroplasts. There is much to suggest such an explanation. Radioactive actinomycin administered to the algae *in vivo* can afterwards be detected not only in the nucleus but also in the cytoplasm where it associates, in the main, with the chloroplasts<sup>11</sup>. The latter are known to contain enough DNA to code for several hundred proteins with a molecular weight of 20,000 (refs. 16 and 17). (This chloroplastic DNA has a base composition which is different from that of nuclear DNA (unpublished experiments).) Actinomycin causes definite morphological and physiological lesions of the chloroplasts (changes in ultrastructure<sup>18</sup>) and loss of photoperiodic rhythm, followed by loss of photosynthetic activity itself<sup>19</sup>. Chloroplasts isolated from anucleate fragments of *Acetabularia* are able to synthesize RNA and proteins<sup>20,21</sup>. Addition of actinomycin to isolated chloroplasts strongly inhibits such syntheses, which require light. The synthesis of chloroplastic proteins must therefore take place in the same way as in whole cells (transcription, translation).

Our colleague D. Shephard<sup>22</sup> has observed that the number of chloroplasts increases in the anucleate fragments. They are therefore capable of self-replication in the absence of a nucleus, but they do divide less frequently in anucleate fragments than in whole plants. This, and the fact that abnormal "dumb-bell" forms occur, suggests that the normal pattern of division is disturbed in the absence of the nucleus.

The increase in the number of chloroplasts in anucleate fragments may explain our recent paradoxical observations<sup>23</sup> that DNA can be synthesized in the absence of the cell nucleus. The DNA content of anucleate fragments of *Acetabularia* doubles in 5–10 days and this increase is blocked by a classical inhibitor of DNA synthesis, hydroxyurea. As we have already seen, this is also true for the DNA content. This simultaneous increase in the amount of both nucleic acids present must reflect the autonomous multiplication of the chloroplasts in anucleate cytoplasm.

Fig. 2. Diagrammatic representation of the polar distribution of morphogenetic substances in *Acetabularia*.

I have already mentioned that the net synthesis of RNA which occurs in the anucleate fragments takes place mainly in the chloroplasts<sup>7</sup>. Using more refined biochemical methods, and notably the fractionation of algal RNA labelled with phosphorus-32 by column chromatography, Janowski<sup>24</sup> has confirmed the important part played by the chloroplasts in the synthesis of RNA by the anucleate fragments. Three distinct kinds of RNA were found to be labelled in the absence of the nucleus: *s*RNA (which is ubiquitous), as well as a ribosomal type of RNA, and a hybrid DNA-RNA, which are associated with the chloroplasts. These findings strengthen the conviction that chloroplastic DNA and RNA can be synthesized in the absence of the nucleus.

Less is known about the ribosomes which are not associated with the chloroplasts, and which I shall call "true" ribosomes: the ribosomal RNAs seem to disappear from the cytoplasm 2 days after enucleation, although ribosomes are still visible under the electron microscope (experiments are in progress). This would suggest a close nuclear control of ribosomes in *Acetabularia*, as in *Amoeba* (where the *r*RNA of anucleate fragments is reduced by two thirds after 1 week<sup>25</sup>). The base composition of the RNAs extracted from true ribosomes and chloroplasts is, however, very different.

Janowski's recent findings<sup>26,27</sup> that anucleate as well as nucleate fragments are capable of synthesizing polysomes are surprising. Polysome synthesis in anucleate fragments is greatly enhanced after these fragments have been subjected to the dark for 2 days, which suggests that the *m*RNAs involved are probably chloroplastic. According to other recent experiments in this laboratory<sup>28</sup>, nucleolar RNA resembles algal nuclear DNA in base composition (A equal to U, G equal to C), whereas in most other cells nucleolar RNA resembles *r*RNA (rich in G). This invites the speculation that, in *Acetabularia*, informational DNA-like RNA, rather than *r*RNA, accumulates in the nucleolus. This might be the informational RNA which migrates to the tip of the stalk.

In the dark (which interrupts photosynthesis and stops the growth and multiplication of the chloroplasts) the structure and chemical composition of the nucleus are considerably altered. It diminishes in volume, the nucleolus (normally sausage-shaped) becomes spherical and vacuolated, and the RNA content is reduced. All these changes, which result from a decrease in the production of energy by the cytoplasm, are reversed when the algae are brought back into the light<sup>29</sup>. Moreover, in another type of experiment, once the cap has been formed, the nucleus degenerates, the nucleolus disappears and the chromosomes repeatedly divide. After several months of interphase, the big vegetative nucleus enters a phase of intense mitotic activity. It gives rise to numerous daughter

nuclei which colonize the alga and ensure its reproduction. Although nothing is known of the stimulus which causes the destruction of the large vegetative nucleus, we do know that this can be prevented indefinitely simply by cutting the stalk each time the cap is about to form<sup>2</sup>.

The nucleus can thus be "rejuvenated" at will by an operation which only affects the cytoplasm. Some kind of control must therefore be exerted by the cytoplasm on the fate of the nucleus. A biochemical analysis of the nature of this control would be most interesting. It now seems certain that the morphogenetic substances described by Hämmerling<sup>1</sup> are in fact stable informational RNAs synthesized in the nucleus. Undoubtedly the chloroplasts also contribute to the astonishing regenerative capacity of the anucleate fragments. It was thus of interest to compare the situation in anucleate systems lacking chloroplasts, such as the eggs of sea urchins and amphibians.

## Sea-urchin Eggs

As Harvey<sup>30</sup> has shown, unfertilized sea-urchin eggs can be separated into two parts by centrifugation in a density gradient (Fig. 4). Parthenogenetic activation of the anucleate halves thus obtained is followed by repeated but irregular cleavage (Fig. 5). Pseudo-blastulae result, and never differentiate. The developmental capacity of anucleate sea-urchin eggs is thus much lower than that of *Acetabularia* stalks. No authentic morphogenesis occurs. All that can be observed is the repeated replication of the centrosomes, the formation of asters around them, and the laying down of cleavage furrows.

The fertilization of sea-urchin eggs and the concomitant stimulation of amino-acid incorporation and protein synthesis raise interesting problems which can only be summarized briefly here (the recent book by A. Monroy offers a full review<sup>31</sup>). The ribosomes of unfertilized sea-urchin eggs are much less active *in vitro* in the incorporation of amino-acids than those prepared from fertilized eggs<sup>32</sup>. The addition of synthetic messenger (polyuridylic acid, for example) to the ribosomes of unfertilized eggs strongly stimulates the incorporation of the corresponding amino-acid, phenylalanine<sup>33,34</sup>. It would therefore be thought that both fertilization and parthenogenetic activation stimulate the synthesis of *m*RNA by the nucleus, for it would then associate with the monosomes of the unfertilized egg, transform them into polysomes, and participate in the burst of protein synthesis. Such has not proved, however, to be the case. It has indeed been found impossible to demonstrate any synthesis of RNA before the 2-4 blastomere stage, either by autoradiography or by biochemical methods<sup>35</sup>. Moreover, actinomycin fails to inhibit protein synthesis or cleavage of fertilized sea-urchin eggs<sup>36,37</sup>. A study of protein synthesis in anucleate fragments<sup>35,38</sup> has further revealed that, whereas the anucleate fragments of ripe unfertilized eggs scarcely incorporate any amino-acids, their parthenogenetic activation causes a massive, almost instantaneous, burst of amino-acid incorporation into proteins. This stimulation actually proves to be more intense in the anucleate than in the nucleate halves. Thus it cannot result from new synthesis of *m*RNA by the nucleus and the facts require some other explanation.

It has not yet been proved that the proteins formed in the anucleate fragments are the same as those found in the whole fertilized egg, though all available information points to such an interpretation. The degree of incorporation of the various amino-acids varies. Yet the ratio between incorporation of different amino-acids in fertilized and unfertilized eggs is invariable<sup>39,40</sup>. Puromycin blocks the incorporation of amino-acid in both cases. Parthenogenetic stimulation alone therefore seems sufficient to induce the synthesis, by both anucleate fragments and intact eggs, of one or more specific proteins. The biological role of these proteins is unknown.

Monroy *et al.*<sup>41</sup> have shown that in fact unfertilized eggs contain in their cytoplasm a reserve of inert *m*RNA, which is formed during oogenesis. These stable messenger RNAs from unfertilized eggs are able to stimulate *in vitro* the incorporation of amino-acids into the proteins of bacterial ribosomes. But they have no stimulatory effect on the ribosomes of unfertilized sea-urchin eggs. The latter can, however, be activated by pretreatment with trypsin, in which event the addition of *m*RNA from unfertilized eggs is followed by stimulation of the incorporation of amino-acids. The main, if not the only, site of the block in protein synthesis in unfertilized sea-urchin eggs is thus the ribosome itself. The ribosomes cannot associate with the messenger RNAs present in the cytoplasm; they are probably coated with basic proteins which prevent the formation of active polyribosomes.

The idea of a control of protein synthesis at the ribosomal level which was first presented in 1962 (ref. 42) is also supported by experiments by Mano<sup>43</sup>, by Mano and Nagano<sup>44</sup> and by Bell and Reeder<sup>45</sup>.

The activation of protein synthesis in anucleate fragments stimulated by parthenogenetic treatment is not yet fully understood. We know, however, that the activated anucleate fragments contain small quantities of functional polyribosomes, actively engaged in the synthesis of proteins (Burny *et al.*<sup>46</sup>). Like whole fertilized eggs, they therefore possess messenger RNAs which are probably identical with those the existence of which has been demonstrated by Monroy *et al.*<sup>41</sup>. They are probably synthesized much earlier by the nucleus (germinal vesicle) of the growing oocyte. This may be concluded from the autoradiographic findings of Ficq<sup>47</sup> and of Das<sup>48</sup>. The various findings can therefore be summarized as follows: An initial period of intense RNA synthesis in the nucleus is followed, at the end of oogenesis, by a phase of repression. At maturation, the RNA synthesized by the nucleus migrates into the cytoplasm and is probably fixed in a stable form to the ribosomes or analogous particles. The ribosomes themselves are inactivated (or repressed) by their association with a protein, which can be digested by trypsin (probably a basic protein).

Fertilization would thus induce the activation or de-repression of the ribosomes, which would be transformed into functional polysomes. It is not without interest to recall that the fertilization of the sea-urchin egg is followed by a transitory, though intense, increase in proteolytic activity<sup>49,50,51</sup>: this increase might very well be responsible for the "activation" of the ribosomes.

Although it seems likely that the stable *m*RNAs present in the cytoplasm of unfertilized sea-urchin eggs originate in the nucleus, one cannot *a priori* exclude a further possible explanation: these RNAs might be synthesized directly in the cytoplasm, perhaps under the control of cytoplasmic DNA.

It has long been known that the unfertilized sea-urchin egg contains a large excess of DNA, as compared with the quantity of DNA contained by the nucleus<sup>51</sup>. We have shown<sup>40</sup> that this DNA is equally divided by centrifugation between nucleate and anucleate fragments. There is thus no doubt that the excess DNA is localized in the cytoplasm. Cytoplasmic DNA has the same density (and thus the same overall base composition) as nuclear DNA; it has a high molecular weight, it exists in a double stranded form<sup>52,53</sup>, and might possibly control the autonomous synthesis of *m*RNA in the cytoplasm. Such a hypothesis seems, however, to be contradicted by the following data: (1) early protein synthesis is insensitive to actinomycin and therefore does not depend on simultaneous DNA-dependent RNA synthesis; (2) it has so far not been possible to demonstrate any early synthesis of *m*RNA; (3) RNA polymerase cannot be detected in the anucleate fragments of unfertilized eggs<sup>40</sup>.

These arguments seem convincing, but need further investigation. Actinomycin might not combine *in vivo* with cytoplasmic DNA; the latter is probably bound

differently to proteins from nuclear DNA and might have less affinity than the latter for actinomycin. Radioactive actinomycin could be used to check this possibility.

We have observed<sup>40</sup> a slight incorporation of uridine, but partially sensitive to actinomycin, in the anucleate fragments of sea-urchin eggs. It would be interesting to find out whether this is indicative of newly synthesized RNA in anucleate fragments or merely evidence of RNA turnover. The origin and intracellular localization of cytoplasmic DNA in sea-urchin eggs also require investigation.

## Amphibian Eggs

The situation with amphibian eggs closely resembles that of sea-urchin eggs. Anucleate eggs show partial cleavage<sup>54</sup>. The replication of centrosomes, the formation of asters and cleavage furrows occur in the absence of the nucleus. Anucleate fragments can synthesize proteins immediately after activation<sup>55,56</sup>. Radioactive amino-acids are incorporated by anucleate activated fragments just as in normally fertilized eggs. Cleavage, unaffected by actinomycin, is interrupted almost immediately by inhibitors of protein synthesis like puromycin and cycloheximide<sup>57</sup>. Thus, cleavage is possible when transcription is prevented, and must be controlled at the translational level. The initiation of RNA synthesis (mainly *m*RNA and *r*RNA) occurs later in amphibian than in sea-urchin eggs; it only starts at gastrulation as compared with the 2-4 blastomere stage in sea-urchins. We do not as yet know whether parthenogenetic activation causes as explosive a burst of protein synthesis in frogs' eggs as in sea-urchins' eggs.

The localization, composition and biosynthesis of cytoplasmic DNA, however, have been more satisfactorily investigated in amphibians. They contain a greater reserve of DNA than sea-urchins (equivalent to several thousand diploid nuclei as compared with a hundred in sea-urchins). Most of this DNA is associated with slowly sedimenting particles, probably yolk platelets<sup>58,59</sup>.

In the past few years, we have tried to locate accurately the DNA present in the cytoplasm of amphibian oocytes<sup>60,61</sup>. Special methods were required to detect it, because it is destroyed by the strong acid hydrolysis used in the classical Feulgen reaction. This difficulty has been overcome by using 1 normal hydrochloric acid in absolute alcohol (instead of in water) to obtain more tempered hydrolysis, and also by using radioactive actinomycin as a cytological marker for the presence of DNA. The results so obtained have led us to the conclusion that amphibian oocytes probably contain at least two kinds of DNA. One is fairly resistant to acid hydrolysis; it accumulates in the perinuclear cytoplasm of the large oocytes and is found in the hyaloplasm after mild centrifugation; it might be bound to mitochondria. It probably originates in the germinal vesicle, as can be judged from experiments using radioactive precursors (it can be labelled with thymidine, uridine and formate).

Fig. 3. Schematic representation of the synthesis of *m*RNA by the nucleus and their migration in *Acetabularia*: (a) normal algae; (b) algae treated by ribonuclease; (c) algae treated by actinomycin.

The nuclear sap of amphibian oocytes indeed contains an excess of DNA probably resembling that of the chromosomes<sup>62,63</sup>. This perinuclear DNA is probably of chromosomal origin, and is released—at least in part—into the cytoplasm when, at the end of oogenesis, the germinal vesicle attains its maximum and begins to regress. The other type of DNA seems to be associated with the yolk, is acidolabile and can only be detected with the aid of radioactive actinomycin. It cannot be labelled with thymidine, but accumulates <sup>14</sup>C-formate when this precursor is administered to oocytes. It may be partly exogenous in origin: the follicular cells and the blood plasma may constitute one of the main sources of yolk DNA. Indeed, the injection of heterologous radioactive DNA (extracted from *Escherichia coli* or phage) into the peritoneal cavity of amphibians is followed by the incorporation of radioactive material first into the cytoplasm and then into the nucleus of the oocyte. Almost intact molecules of DNA actually seem to be entering the oocyte (unpublished results of Y. Kong and E. Sempinska).

Perinuclear DNA, which apparently is itself derived from the nucleus, might have a genetic function. Yolk DNA, on the other hand, is more likely to constitute a simple reserve material of lower molecular weight, a supply of the precursors required for DNA synthesis before nuclear multiplication during development.

Dawid<sup>64</sup> has investigated the chemical and physical properties of DNA in amphibian eggs (frogs and *Xenopus*). The resemblance, as regards density and molecular weight, between the cytoplasmic DNA of amphibian eggs and the nuclear DNA of the liver of the same species seems to be fairly superficial. Only 0.1–5 per cent of hepatic DNA is homologous to cytoplasmic DNA. (According to Shmerling<sup>65</sup>, the cytoplasmic DNA of sturgeon eggs has a molecular weight of 800,000 and a high degree of homology with the DNA of spermatozoa.) The latter small fraction might correspond to the perinuclear (mitochondrial) DNA of the oocyte. But the homology found between a minute fraction of amphibian egg DNA and adult chromosomal DNA poses, on the other hand, the problem of the biological significance of the cytoplasmic DNA in eggs.

It is as yet impossible to decide whether the cytoplasmic DNA of these eggs can be synthesized autonomously in the absence of the cell nucleus: in the anucleate fragments of the sea-urchin, we have observed a slight incorporation of thymidine under conditions in which every possible precaution had been taken to reduce bacterial contamination to a minimum. A short note by Mezger-Freed<sup>66</sup> affirms that the DNA content of anucleate unfertilized frog eggs may double in a few hours. This work is now being repeated in our laboratory.

The complexity of the problems raised by the presence of cytoplasmic DNA in amphibian eggs appears even

greater when one takes into consideration the observations we recently made on the behaviour of DNA during the maturation of the oocyte.

The maturation of toad or of *Xenopus* oocytes can be obtained *in vitro* by placing the large oocytes in Ringer solution containing minced hypophyses<sup>67</sup>. This technique has the advantage of making it possible to follow the action of the hormone on an isolated oocyte. After treatment for 3–4 h, the nuclear membrane presents, on the vegetative side, many invaginations extremely rich in RNA. Simultaneously, the nuclear sap becomes basophilic: according to preliminary electron microscope studies, this basophilia seems to be caused by the synthesis of ribosomes, or an invasion of the nuclear sap by the latter. These changes probably correspond to real synthesis of RNA. Brown and Littna<sup>68,69</sup> have shown by biochemical techniques that appreciable quantities of heterogeneous RNA (presumably mRNAs) are synthesized during the maturation of *Xenopus* oocytes. Extensive protein synthesis also occurs during maturation<sup>70</sup>; it is inhibited by actinomycin and puromycin (ref. 71 and personal observations).

When the nuclear membrane begins to break down, a number of Feulgen-positive granules appear at the site of the disintegration of the nuclear membrane. DNA synthesis, which is evidenced by considerable incorporation of thymidine into the breaking down germinal vesicle (unpublished), thus follows very closely the synthesis of RNA.

After treatment with hormone for 7–8 h, the Feulgen-positive particles collect at the animal pole and usually assemble in the cortex to form two or three large inclusions which are intensely coloured with the Feulgen reaction. There is no doubt that these cortical grains contain much more DNA than the chromosomes.

The part played in development of the DNA which forms in the cytoplasm when, during maturation, the nuclear sap and the cytoplasm mix, after having been separated for 2 or 3 years by the nuclear membrane, is not yet known. The fact that this DNA is found in the cortical granules raises the question of whether it accumulates in the "grey crescent" after fertilization of the egg. The removal of the cortex of this grey crescent is known to stop normal morphogenesis (only cleavage is possible after this operation), while the grafting of a supplementary dorsal cortex into the ventral half of the fertilized egg results in the formation of double embryos (Siamese twins<sup>72</sup>). It seems likely that, as I have suggested<sup>73</sup>, the dorsal cortex of the fertilized egg controls derepression (that is to say, RNA synthesis) in the nuclei of the dorsal lip of the blastopores (organizer).

The existence in the dorsal cortex of amphibian eggs of particles containing DNA may explain the very curious experiments recently made by Curtis<sup>74</sup>; his results, which show that the cortex possesses its own heredity, are difficult to explain except by admitting the presence in the dorsal cortex of particles capable of self-replication. Perhaps these are the DNA particles which we saw appearing in the cytoplasm after interactions between the nucleus and the cytoplasm at the time of the maturation of the oocyte.

One may also ask whether the cytoplasmic DNA of nuclear origin plays a part in determining the fate of the germinative plasma; in fact, ultra-violet irradiation of the vegetative pole of amphibian eggs is known to provoke sterility in the irradiated embryos<sup>75</sup>.

There is therefore no lack of theories concerning the hypothetical role of cytoplasmic DNA in amphibian eggs. For the time being, however, there is a scarcity of conclusive facts; fortunately both biochemical and cytochemical methods now exist which may enable these problems to be solved.

It is worth drawing attention to some analogies between amphibian eggs and *Acetabularia*. The proportion of nuclear to cytoplasmic volume controls the entry of the

Fig. 4. Ultracentrifugation of unfertilized sea-urchin egg (E. B. Harvey, 1932).

Fig. 5. 13 h non-nucleated morula and 3-day non-nucleated blastula (E. B. Harvey, 1936).

big *Acetabularia* nucleus into mitosis. When the cytoplasm reaches a certain volume, it seems to repress the synthesis of nuclear RNAs (transcription) in favour of DNA synthesis (replication). Treatment of amphibian oocytes with hypophyseal hormones interrupts, after a brief period of stimulation, the synthesis of nuclear RNA. The synthesis of extrachromosomal DNA begins at just that moment. The control mechanisms repressing the synthesis of RNA and inducing the replication of DNA thus come into force during maturation. They continue to function throughout cleavage, which is characterized by repeated multiplication of the chromosomes in the absence of any considerable synthesis of rRNA or mRNA<sup>67,76,77</sup>.

Experiments by Gurdon and Brown<sup>78</sup> and by Graham *et al.*<sup>79</sup> show that the cytoplasmic mechanisms regulating the synthesis of the two nucleic acids also come into force when adult nuclei are introduced into unfertilized, activated and enucleated eggs: if these nuclei were synthesizing rRNA, they would stop doing so after transplantation. If nuclei from adult organs no longer synthesizing DNA are injected into activated and enucleated unfertilized eggs, they immediately start to incorporate thymidine.

Thus, it is certain that the state of the cytoplasm of the eggs regulates the beginning of their development and the orientation which the synthesis of nucleic acids (DNA and RNA) is going to take. Repressors, which prevent the synthesis of RNA on the matrix of DNA, must exist in the cytoplasm of the egg. Their presence does not affect the synthesis of DNA or of proteins. In sum, during the preliminary stages of development, the transcription of new genetic messages does not take place; on the other hand, those which already exist are transcribed whereas the DNA replicates itself. Such repressors as those hypothesized here have yet to be identified. It is interesting, however, to note that Yamana *et al.*<sup>80</sup> have recently shown the presence, in blastulae of *Xenopus*, of a specific inhibitor of ribosomal RNA synthesis.

Embryology is undoubtedly moving toward new "molecular" horizons. Uncertainty as to the role of cytoplasmic DNA, stable messenger RNA and ribosomes will be dissipated in the coming years. The future will also confirm whether or not, as we suggested in 1962 (ref. 42), the ribosomes of the egg play a less passive part than that usually attributed to them, whether they intervene directly in the reading of the genetic message and whether one of the factors of embryological differentiation is implicit in a competition within a heterogeneous population of ribosomes. Whatever the answer to these questions, molecular embryology is clearly moving ahead with new impetus, and is now ready to solve the great problems raised by experimental embryology: preformation, epigenesis, regulation, induction, and so forth.

I thank Dr. P. Malpoix for her translation of this text into English. The experiments from my laboratory received financial support from Euratom and the Centro nazionale delle Ricerche.

## BOOK REVIEWS

### HAPPENINGS ANALYSED

#### The Statistical Analysis of Series of Events

By D. R. Cox and P. A. W. Lewis. (Methuen's Monographs on Applied Probability and Statistics.) Pp. viii + 285. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1966.) 50s. net.

THE times of occurrence of accidents, of computer failures, and of the pulses in a nerve fibre are among the phenomena that give motives for the theory in this book and provide examples of its application. For the phenomena considered, stochastic models, based on the idea of point events occurring in a haphazard way in space or time, can be usefully employed. It is towards the problems of statistical inference about these stochastic point processes that the book is primarily directed.

Books about the probability theory of stochastic models have proliferated in recent years, but the subject of inference about these models has been much less widely covered. This is partly because in current research the building of the models has run ahead of the statistical analysis of the situations to which they may apply. Nevertheless, a good deal is now known and gratitude is due to the authors for making much of it available in a single volume. This volume is the largest so far to appear in Methuen's series of monographs, and the reason is that although the authors' primary purpose is to deal with statistical inference, they find it necessary to present substantial accounts of the probability theory of many of the processes as well. The completeness that this gives certainly justifies the extra size of the volume, and will make it a useful tool in the hands of anyone who has to deal with problems involving stochastic processes of point events.

The introduction of the book includes several problems from various fields of application, and this is followed by a consideration of the Poisson process, which illustrates a number of the points that have to be dealt with in handling more complex processes, and of course these often arise when one observes a departure from the Poisson characteristics of "pure randomness" in a series of point events. Regression analysis and other methods of dealing with a trend in the series are covered in Chapter 3, and the rest of the book deals with stationary processes. The chapter on stationary point processes gives general results including forward recurrence times and some consequences of the relation between counts of events and times between events. The estimation of second-order properties of stationary processes which follows includes spectral estimates, and estimates of first and second moments, for intervals between events, and counts of events. The sixth and seventh chapters cover renewal processes, some related significance tests and generalizations of renewal processes. Some models useful in textile technology, computer failure studies, and road traffic movement appear here. Superposition of processes concerns the pooled output of several series of simpler form, and an application to nerve pulse data. In the comparison of rates of occurrence in Chapter 9, applications to accident rates and failure of air-conditioning equipment and computers are dealt with. Finally, there are some generalizations, where a brief introduction to events in several dimensions and events of more than one type is given.

The book ends with several appendixes, including some data for models which have been discussed in the text, and a set of thirty-eight exercises and further results. It will be useful to workers in numerous fields of application, and essential to any student of stochastic processes and their statistics, for whom at present-day prices it is good value at 50s. W. A. O'N. WAUGH

### PROPULSION WITHOUT WHEELS

#### Propulsion Without Wheels

By E. R. Laithwaite. Pp. x + 273. (London: The English Universities Press, Ltd., 1966.) 63s. net.

To anyone previously unaware of the author's interests the title may be rather misleading. Only electromagnetic means of propulsion are considered, and, although the emphasis is very much on linear machines, propulsion is by no means the only, or even the major, topic. The main limitation on subject matter seems to have been that it should be both interesting and unusual, and the applications described range from levitation to impact extrusion.

The machines considered present some of the most difficult analytical problems that an electrical engineer could expect to encounter. Yet with a minimum of mathematics and with considerable use of simple sketches and diagrams, the material is generally presented so clearly and carefully that even readers with only a rudimentary knowledge of electricity and magnetism should be able to follow most of it. At the same time some of the phenomena described are so intriguing, and the author's approach so stimulating, that even the more knowledgeable reader will find the book interesting.

For many the most fascinating parts of the book will be those which deal with the working models that Professor Laithwaite has demonstrated on television. Not only are the various experiments described, but very full design and constructional details of the models are given at the end of each chapter. Professor Laithwaite states in the preface that his aim in writing the book was not only to inform about linear motors and their application, but also to help science teachers and amateur experimenters to design and build good working models of these. The book fulfils these aims admirably and must surely arouse yet more interest and enthusiasm for this subject which the author finds so fascinating. R. BROWN

### HYPERSONIC FLOW

#### Fundamental Phenomena in Hypersonic Flow

Edited by Gordon J. Hall. (Proceedings of the International Symposium sponsored by Cornell Aeronautical Laboratory.) Pp. viii + 354. (Ithaca, New York: Cornell University Press; London: Oxford University Press, 1966.) 100s. net.

As part of the centenary celebrations of Cornell University, the Cornell Aeronautical Laboratory sponsored a symposium on hypersonic flow in June 1964. The present volume contains the thirteen invited lectures as well as comments by appointed reviewers and discussions from the floor. The organizers are to be congratulated for bringing together such an array of talent in the field. The contributions are all of high standard and pleasantly combine critical review material with new results covering the major branches of the field of hypersonic research.

H. J. Allen reviews the aerodynamic heating problems of re-entry and shows how careful observations of meteors can provide information at entry speeds beyond those at present attainable in earth-bound experimental facilities. J. A. Fay reviews heat transfer theories in the velocity range 10–20 km/sec and extends them to obtain estimates at higher speeds. Van Dyke "revisits" the blunt-body problem and demonstrates that it is possible to improve the analytical methods and, thus, to use computers more efficiently. M. P. Guiraud contributes further to the controversy between himself and R. Vaglio-Laurin about asymptotic expansions for power law bodies.

Viscous flows are discussed by H. K. Cheng, who presents work on slip effects and shock structure of the bow wave and obtains flow patterns at low Reynolds numbers, and by N. C. Freeman, who looks at the diffusion of species

in hypersonic boundary layers, obtains a general solution as a Mellin transform and investigates special cases. Three papers are concerned with relaxation effects and chemical kinetics. A. G. Gaydon reviews methods of temperature measurement with emphasis on the sodium-line reversal method and presents new experimental results. H. W. Palmer reviews chemical kinetics problems which can be studied in the shock tube, and M. Camac presents a thorough investigation of the structure of shock waves in carbon dioxide in the Mach number range 5–25.

R. Goulard contributes to radiation gas dynamics by exploring the analogy between radiation transfer and the neutron-flux problem. In the field of rarefied gas dynamics S. F. Shen develops a method for handling flows with solid boundaries based on hydrodynamic equations in which the Navier–Stokes stress-strain relations and the Fourier heat conduction law are replaced by more general expressions. Y. S. Pan and R. F. Probst discuss the flow past a flat plate and the transition from ordinary continuum boundary-layer flow far downstream to almost free-molecule flow near the leading edge. In the last paper L. Lees and H. Gold study the instability of laminar wakes. Theoretical calculations are compared with experimental results on transition to turbulence.

Because of the time lapse between the symposium and the publication of the proceedings most of the new results presented will now be well known to active research workers who will nevertheless undoubtedly find the volume useful for reference. It should also serve almost as a text-book for newcomers, in particular those who prefer short stories to the full-length novel as contained in the ordinary text-book. The editor and Cornell University Press have done a splendid job. Rarely are the proceedings of a symposium presented as attractively as in this case.

N. H. JOHANNESSEN

## WELSH NATURALISTS

### The Snowdonia National Park

By W. M. Condry. (The New Naturalist: a Survey of British Natural History.) Pp. xvii+238+28 plates. (London: William Collins, Sons and Co., Ltd., 1966.) 30s. net.

THIS is the forty-seventh book issued in Collins's main "New Naturalist" series—the most impressive publishing feat in the biological field in modern times—and the sixth of the series to deal with a region. One of the previous five, indeed, was also about Snowdonia, so that it must be said at once that this is an entirely new book by a different author. It has all the merits to be expected from a book by a single author and is in many ways a model of how a regional natural history should be written.

The author lives just outside the southern boundary of the region, and is clearly thoroughly familiar with it. The boundaries are those appointed by the National Parks Commission, and run south from Conway to the River Dovey, and from the Berwyns in the east to Moel Hebog and the Snowdon massif in the west. Here, especially on either side of Llanberis Pass, is some of the classic ground of British natural history. The Merioneth part of the park is much less widely known, and this part of the book is therefore the more valuable.

The wildlife riches of Snowdonia make it the most important single region in Wales, and almost the most important upland region south of the Highland Line—but how can one in any useful sense grade in importance three such splendid mountain areas as the English Lakes, Upper Teesdale and Snowdonia? It has one unique British plant, *Lloydia serotina*, which is found nowhere else nearer than the Alps, a good many other alpine in their most southerly British sites, an endemic fish in the gwyniad *Coregonus pennantii*, choughs breeding inland and several

feral herds of goats. The fine dune systems of its Merioneth coastline are especially rich in plant life, and its hanging oakwoods are also of the greatest importance in maintaining the diversification of wildlife which is one of the chief fascinations of the British countryside.

A chapter on conservation deals faithfully with the Nature Conservancy and its fourteen national nature reserves (seven woodland, five mountain and two dune), but evidently must have been written before the foundation of the North Wales Naturalists' Trust, which is not mentioned. Important as the conservancy undoubtedly is, the task of preserving the rest of Snowdonia's important habitats will fall largely on the trust, which already has three small reserves in the area.

Three of the dozen national parks in Britain now have their New Naturalist volume—the others are Dartmoor and the Peak District—and it is much to be hoped that the editors of the series will succeed in producing volumes of equally high standard for the remainder. With such a guide in his hand, the naturalist will double or treble the pleasure and knowledge he gains from a visit to a national park.

R. S. R. FITTER

## POLISH PLANT LIFE

### The Vegetation of Poland

Edited by W. Szafer. (International Series of Monographs in Pure and Applied Biology, Division: Botany, Vol. 9.) Pp. xxiii+738. (London and New York: Pergamon Press, Ltd.; Warsaw: PWN—Polish Scientific Publishers, 1966.) 120s.

THIS book is a translation from the Polish of *Szata roślinna Polski*, and is a symposium produced by eight workers at Cracow edited by the professor of botany in the Jagellonian University. Two chapters of the original work, dealing with detailed descriptions of the Polish lowlands and mountains, are omitted from the translation as being of less general interest. This is a pity, because in a work specifically devoted to the vegetation of Poland one looks especially for Polish particularities.

For a summary of the contents one can hardly do better than quote from the preface: "A brief outline of the history of phytogeographic research in Poland is followed in natural sequence by chapters dealing with factors affecting the geographical distribution of plants and, separately, with the influence of man and his economic activities . . . and with the role played by other biotic factors on the vegetation and flora. Next we have information concerning the geographical and historical elements of the Polish flora and its statistics. Then there are two chapters . . . giving a survey of plant communities on land and in the Baltic Sea. The following chapters deal with the history of the origin and development of the Polish vegetation and, separately, with the history of the more important cultivated plants. The final chapter presents analyses of the vegetation of Poland, descriptively and cartographically."

It is one of the peculiarities of some of the eastern European countries, and perhaps of Poland in particular, that botanical investigation has become centred on phytogeography and ecology; in most countries in western Europe, largely because of an army of enthusiastic amateurs, preoccupation with taxonomy has produced a notable series of systematic floras which are largely lacking in Poland. The present work demonstrates that there are historical reasons for this, apart from the transitional place occupied by Poland between the varied topography and geology of western and southern Europe and the monotonous plains of the east and north-east—a fact which provides opportunities for many interesting studies in species with their easterly and westerly limits of distribution in Poland. This phytogeographical trend is continued and emphasized in the present work. A vast amount of information on Polish phytosociology, geology,

climate, soils and most relevant subjects is presented in a lucid and readable manner, freely illustrated with species and habitat photographs, maps (a schematic geological map is particularly useful), profile diagrams and all the necessary clarifying media. A large and detailed map of the geobotanical division of Poland is contained in a pocket in the back cover, and is printed with exemplary clarity. The translation is wholly admirable except in one or two instances where presumed literal translations of vernacular names occur. For example, on p. 580, *Pinus cembra* L., of which the universally employed English name is "arolla pine", is referred to as the "stone pine"—a name equally universally applied by English speakers to *P. pinea* L.

The space occupied by the various sections is somewhat uneven—for example, the review of terrestrial and freshwater communities, much of which will contain little new to most ecologists, occupies almost one third of the entire book; on the other hand, that of the vegetation of the Baltic is one of the smallest, even allowing for the obvious limitations here. Although there are some references to bryophytes, lichens and fungi, it is unfortunate that cryptogams do not feature more in this book, because in any community no one plant is more significant than any other. Perhaps this limitation is a function of a lack of Polish taxonomists! It is the more regrettable because some species, for example the moss *Tortula velenovskyi* Schiffn. as shown by Waclawska, have as interesting a "Central European" distribution as any flowering plant.

One of the most interesting chapters is that concerned with man's influence on plant life, dealing as it does with the retreat of many interesting species before his usually savage over-exploitation of the land and the influx of introduced, mainly weedy species in his wake. The development of crops is less satisfactory because, although the author of this section discusses the possible wild origins of various cereals, there is no mention of current ideas about the origin of *Triticum aestivum* L. emend. Fiori et Pal. (the correct name of *T. vulgare* Vill.) as a product of *Triticum monococcum* L., *Aegilops speltoides* Tausch and *A. tauschii* Coss., or of the very interesting discussion in recent years concerning the ancestry of the six-rowed barley.

This thoroughly commendable book closes with an exhaustive bibliography, frequent references to which considerably enrich the text. C. C. TOWNSEND

## LIMB ISCHAEMIA

### Pathology of Limb Ischaemia

By J. Henry Dible. (Pathological Monographs, No. 3.) Pp. vii+100. (Edinburgh and London: Oliver and Boyd, Ltd., 1966.) 57s. 6d. net.

A DISORDER of such commonplace occurrence as limb ischaemia is one which lends itself to exploration in depth and is thus an ideal subject for a monograph such as this. The other factor which contributes even more to the undoubted success of this book is the life-long enthusiasm of the author for his subject—an enthusiasm which he succeeds in communicating to the reader.

In his preface, Professor Dible relates how he devised an improved technique for injecting limb arteries with a radio-opaque mass, as a result of an abortive investigation into gas gangrene, planned during the Second World War. This technique he used in subsequent years to study spontaneous limb ischaemia caused by thrombosis, atherosclerosis and Buerger's disease, and this book sums up his observations. The author sets the stage with three opening chapters which deal with fundamental matters, such as arterial structure, arterial nutrition and the vasa vasorum, and age changes in arteries. Here the reader is quickly made aware of the many points of uncertainty in our basic knowledge, often glossed over in

pathology textbooks. There follows a detailed consideration of atherosclerotic occlusive disease and thromboangiitis obliterans. The numerous excellent illustrations include radiographs of injected limbs, photomicrographs and diagrams, which illustrate clearly the system of arterial arcades found in limb arteries. It is this anatomical arrangement which explains why gangrene is a late development, even where multiple arterial obstructions are present. The relative freedom from disease of the peroneal artery is one of the many interesting facts brought to light in these investigations.

By his painstaking studies, Professor Dible has done much to narrow the field of ignorance, and this book will be of interest to many besides pathologists and vascular surgeons. The book is well produced, but it is a pity that it is so highly priced. A. G. STANSFELD

## LIVES OF SCIENCE

### Asimov's Biographical Encyclopedia of Science and Technology

By Isaac Asimov. Pp. x+662. (London: George Allen and Unwin, Ltd., 1967.) 63s.

HERE is a chronological sequence of biographies of men of science from ancient Egypt to the space age. Some of the subjects seem to have been chosen less for their science than for their fame; the meaning of science is being stretched to include anything connected with the advance of knowledge and with technical achievement. One might expect to find the eighteenth century theatrical designers and the cloud machines here if there had not been so many of them. The subject of the first entry in the book is Imhotep, the Egyptian scholar, whose dates seem to be uncertain, but who flourished between 2980 and 2950 B.C. He was probably the architect of the earliest of the pyramids and was well known as a man of healing. By Ptolemaic times he had been deified, an honour to science which has not been repeated. The Greek and Roman philosopher-scientists and engineers receive ample mention; and Tsai Lun, the supposed Chinese inventor of paper, is celebrated as perhaps the only eunuch to claim a key position in the history of science. With the end of the classical era and the coming of the dark ages, learning was maintained by the monks, such as the Venerable Bede, who compiled his history of early Anglo-Saxon England largely from the writings of Pliny. Bede was also concerned in the controversy about the dating of Easter.

There is plenty more such detail in this book, which is intended, as the preface implies, as a history of science, told biographically. Its value seems to be limited—although writers of obituaries might glean some useful information from the later entries—when critical biographies of scientists abound. A disjointed collection of personal histories such as this is surely not the most interesting way of presenting a comprehensive history of science. MARY LINDLEY

## MAN AND INSECTS

### Insects and Hygiene

The Biology and Control of Insect Pests of Medical and Domestic Importance. By J. R. Busvine. Pp. xi+467. (London: Methuen and Co., Ltd., 1966.) 100s. net.

THE greater part of this book is a factual account of the biology and control of the insects and allied arthropods likely to be encountered in association with man—as parasites, for example, lice, bed-bugs, fleas and mites; as vectors of disease, for example, houseflies and mosquitoes; as pests of his food such as grain weevils; or in his home,

for example, furniture beetles and clothes moths. A smaller initial section serves to introduce the subject of entomology with the structure, classification, anatomy, physiology and ecology of insects all dealt with at some length. In between the two sections of the book are three important general chapters concerned with all the different aspects of preventive and control measures, including legal and commercial aspects.

The numerous insecticides available today are described in some detail with chemical formulae, formulations and methods of application all given prominence. Resistance to insecticides and concern about the widespread contamination of man's environment with stable toxic chemicals has led in recent times to consideration of other methods of control. Some of these involving genetical manipulations and the release of sterilized insects are referred to, as well as the use of parasites and predators.

This is the second edition of a work first published in 1951 and then aimed at those concerned with domestic hygiene in Great Britain. Now it is considered equally applicable to most of the temperate regions of the world. With only a little more elaboration it could have been made applicable to the tropics as well. Already many references are made to the importance in the tropical hygiene field of many of the pests dealt with, and it can be argued that insect pests are hardly of sufficient consequence in public health considerations in temperate climates to warrant a book as detailed and well presented as this one.

G. DAVIDSON

## FIBRE SCIENCE

### Man-Made Fibres

By R. W. Moncrieff. Fourth edition. Pp. ix + 742. (London: Heywood Books; New York: John Wiley and Sons, Inc., 1966.) 75s. net.

THIS impression of *Man-Made Fibres* carries on the general pattern of its preceding editions in standard and presentation. With the passing of time the information available about man-made fibres is increasing, and so is the number of man-made fibres available. Hence the volume of the publication is increasing, although this second impression contains only slight variations on the 1963 edition.

The great virtue of this publication is the uniformity of the standard of presentation. The work purports to be a general description of man-made fibre manufacture and properties, and the early chapters which deal with the fundamentals of "fibre science" are simply presented. X-ray structure is given an elementary treatment, as is viscosity of polymer solutions and also the general physical properties of fibres. The techniques of infra-red and electron microscope studies of fibres might have had some mention in a new edition, and this could well have applied also to chromatography and other new chemical and physical techniques.

It is unlikely that any normally used man-made or regenerated fibre is not mentioned and a greater or lesser description of its properties given. Allied groups of fibres are treated chapter by chapter, and in an appendix table the known trade-names of various yarns are given. At the end of each chapter an additional reading list is given which is probably of great value. As a work of reference the book suffers from the fact that no adequate reference system is introduced. The text is almost the sole source of information, but the information is voluminous. Having passed through numerous editions since its introduction, there is little doubt that it is finding increased use in textile circles, both industrial and academic. Provided, therefore, that the reader is not looking for extensive reference coverage, the book can be recommended to all sections of interest in man-made fibres.

F. H.

## ADVANCES IN THE ANALYTICAL SCIENCES

### Analytical Chemistry

Vol. 4. Edited by Carl E. Crouthamel, D. C. Stewart and H. A. Elion. (Progress in Nuclear Energy, Series 9.) Pp. 166. (London and New York: Pergamon Press, Ltd., 1966.) 70s. net.

THIS, the fourth volume in the *Analytical Chemistry* series of *Progress in Nuclear Energy*, contains four useful review articles, two of which might be said to be on the periphery of the subject and two nearer to the main area of interest.

The first article, on solid state charged particle detectors, by N. J. Hansen, is one of the peripheral type but nevertheless is valuable in that it gives a broadly based review of the solid state and nuclear physics as well as of the electronics theory behind the use of these detectors in nuclear spectroscopy. The applications are described only briefly and, as the title indicates, are limited to the detection of alpha particles, deuterons, protons, heavy ions, electrons and fission fragments.

Advances in neutron activation are discussed by V. P. Guinn in the second article, which though short (only fourteen pages) really does describe advances made in the period 1958-64 in this now widely used method. It discusses improvements in equipment, that is neutron sources, pulse-height analysers and counters; advances in technique, and new applications in a range of industry and science including scientific crime detection and space studies. Though very good in what it covers, the article was presented at the Geneva Conference in August and September 1964, and describes only those advances made in the United States. It seems a pity that what was quite properly presented as a national contribution to a United Nations conference is now given permanence two years later in a series which prides itself on its international and up to date coverage.

Slow electron interaction with adsorbed gases is discussed by D. Lichtman and R. B. McQuistan in the third, and the other "peripheral", review. It describes one approach to the problem of providing information about the surfaces of materials, especially metals, by bombardment with electrons (and possibly photons and ions) in conditions where the atoms, molecules and ions desorbed during the bombardment can be identified by mass spectrometric analysis. The examination of surfaces is a very important area of growth in the analytical sciences, and the article is very useful in giving information about one approach to the problems.

Use of neutron generators in activation analysis is the subject of the fourth review by J. E. Strain. This again is quite short (twenty pages) but is valuable and realistic. After describing the general requirements and how these are met, several examples of neutron generator application are given, by element, with some excellent practical information on sensitivity attainable, interferences, advantages and disadvantages. This article will be of much interest to the increasing number of industrial users of neutron generators, though unfortunately it does not cover the fairly recent sealed-tube generators where shielding can be so much easier.

Altogether a useful assembly of topics, the present volume continues to show the wide range of interests of modern analysis.

A. A. SMALES

**ERRATUM.** In the review by Dr. H. Lehmann last week (*Nature*, 213, 552; 1967) of Georges Sandoz's *Serum Proteins in Health and Disease*, lines 4 and 5 of the first paragraph should read "that there are few people left who—like the author—span the history from the past to the present day". In the printed version, "like me" was unfortunately substituted for "like the author".

## OBITUARIES

### Professor Sir Thomas M. Cherry

SIR THOMAS CHERRY, who died in Melbourne on November 21, 1966, at the age of 68, played a leading part in university affairs in Australia for more than thirty years. He was widely known and respected as the country's most distinguished mathematician and a man of keen insight and unusual force of character.

After taking his first degree at Melbourne he studied at Cambridge and obtained both his Ph.D. and a research fellowship at Trinity College in 1924. During the period 1922–28 he worked on the theory of ordinary differential equations, and gained a mastery of the subject which was later transmitted to generations of undergraduates. He made a number of significant contributions in particular to knowledge of the properties of Hamiltonian systems of differential equations and of their solution curves. This subject of research suited him well; it demanded precision of thought, skill with mathematical analysis of the kind which leads to general results, and a taste for the austere beauty of "rational mechanics", all of which he could supply. In 1929 Cherry was appointed professor and head of the Department of Mathematics at the University of Melbourne, and the central phase of his life began. For the subsequent thirty-four years he devoted himself unsparingly to the teaching work of the department. The modern means by which a head attempts to improve and extend the teaching provided by his department is to press for more staff; Cherry's way was to do much of the teaching himself and (unconsciously) to inspire his staff by his own high standards of thought and discipline. He gave lectures on many topics, in both pure and applied mathematics (which for him were not divided); epsilon-analysis, projective geometry, celestial mechanics, hydrodynamics, whatever was needed, and at all levels. He had a dry manner and lacked small talk, but the clarity of his exposition, the breadth of his knowledge of mathematics and mathematical physics, and his obvious integrity made an indelible impression on the many honours mathematics students who passed through Melbourne in this period. In accordance with his belief that teaching was his primary task, Cherry also served as chairman of the Mathematics Committee of the Schools Board for twenty-three years, when he was responsible for the mathematical syllabuses in secondary schools, and did much in support of the Mathematical Association.

During the war Cherry acted as a consultant to several government establishments, and his contact with the Aeronautical Research Laboratories generated an interest in gas dynamics which led to two further sequences of papers. One of these sequences dealt with asymptotic expansions for functions occurring in gas dynamics. The other was concerned with the use of the hodograph equation and a family of exact solutions of two-dimensional flow of which a part may be supersonic. Such problems of transonic flow are very difficult, but his remarkable mastery of analytical methods enabled him to make a number of decisive contributions. Cherry never sought recognition of his research, but these papers on gas dynamics were in the main stream of current work and he was elected to the Royal Society of London in 1954.

Further recognition of his high standing in Australian scholarship came with his appointment in 1956 as foundation President of the Australian Mathematical Society and in 1961 as President of the Australian Academy of Sciences,

and again in 1965 when he was knighted. Cherry retired at the end of 1963, and was appointed emeritus professor of applied mathematics. He was still exceptionally vigorous, and everyone expected that the years of retirement would yield much creative thinking and writing, in addition to active work on the council of the new Latrobe University, but they were cut short by heart trouble. The value of his professional work and his contributions to science cannot be measured by his list of publications. He knew much more than he ever wrote, and his influence was transmitted more by personal contact than by the printed word. That it was a unique and powerful influence any mathematician from Melbourne will testify.

G. K. BATCHELOR  
E. R. LOVE

### Professor A. D. Ross

ON December 14, 1966, at Albany, Western Australia, Professor Alexander David Ross died peacefully after a short illness at the age of 83.

Born in Glasgow in 1883, Ross had a distinguished career at the University of Glasgow, where in 1905 he was Thompson Research Fellow. In 1906 as Houldsworth Research Fellow he studied at the University of Göttingen, and in 1908 was appointed lecturer in natural philosophy at Glasgow. His research interests were in the fields of magnetism and spectroscopy. In recognition of his researches the University of Glasgow in 1914 awarded him the Kelvin Medal, of which he was the first recipient.

On the foundation of the University of Western Australia, Ross was appointed in 1912 to the chair of mathematics and physics. He arrived in Perth to take up duties early in 1913, and in that year classes commenced. When in 1929 mathematics and physics were separated he took over the chair of physics until his retirement in 1952. Except for a visit to Europe during the First World War and again in 1951, Ross gave uninterrupted service as teacher, scientific investigator, consultant and administrator over a period of nearly forty years. He was the last in office of the eight foundation professors. By his students he will be remembered particularly as a teacher, clear in exposition, thorough in treatment and considerate to all who were zealous in their aspiration to academic distinction.

Professor Ross played a distinguished part in building up the university tradition in Western Australia as professor of mathematics and as professor of physics, and in the numerous posts he has held in scientific and other organizations within and without the university. He and other professors, coming from abroad in the early days of Australian universities, had the distinction of being agents for the transmission of higher educational standards and sound cultural traditions to the state of Western Australia.

The wide range of his scientific interests in Australia is indicated by the many posts which he held at various times during the occupancy of his chair at the University of Western Australia. These posts included terms as president of the Australian Branch of the Institute of Physics and the Royal Society of Western Australia; he was local secretary of the Australian and New Zealand Association for the Advancement of Science, and chairman of the Western Australian Division of the National Research Council. Ross always lived an active life, and carried over into retirement some of his responsibilities, particularly his association with the Pan-Indian Ocean Science Association, of which he was founder and honorary secretary, and with the National Association of Testing Authorities. During the Second World War, Ross was a member of the Commonwealth Munitions Panel, deputy director of camouflage for Western Australia and consulting physicist to the Royal Australian Navy. He was made a C.B.E. in 1949.

JOHN SHEARER

# Palmer Ridge: a Section through the Upper Part of the Ocean Crust?

by

J. R. CANN\*

Department of Mineralogy, Downing Place,  
Cambridge

B. M. FUNNELL

Department of Geology, Downing Street,  
Cambridge

Palmer Ridge, part of the Kings Trough feature, N.E. Atlantic, consists of metamorphic and igneous basement with a cover of Tertiary sediments uplifted and intruded by a mass of serpentinite. The basement was formed about 60 million years ago at the mid-ocean ridge crest, and the uplift of the ridge and opening of Kings Trough occurred about 27 million years ago.

FOURTEEN successful dredge hauls were made in 1965 and 1966 from R.R.S. *Discovery* of the National Institute of Oceanography in a small area ( $18 \times 18$  km) of Palmer Ridge, an element of the Kings Trough feature in the N.E. Atlantic. This article gives a preliminary account of the rocks recovered and a possible explanation of the geological structure of Palmer Ridge.

Kings Trough<sup>1</sup> is a feature north of the Azores about 200 miles long running approximately N.W.-S.E. It consists for the most part of a central depression flanked by ridges on either side: the seamount Ant-Altair forms part of the southern ridge. At the S.E. end, around  $42^\circ$  N.,

\* Present address: Department of Mineralogy, British Museum (Natural History), Cromwell Road, London, S.W.7.

$20^\circ$  W., two deeps, Peake and Freen Deep, are found, flanked by small ridges to the north and south and separated by a ridge rising to about 1,300 fathoms which is Palmer Ridge (see Fig. 1).

Fig. 2 shows the results of a detailed bathymetric survey of the small area of Palmer Ridge and the dredge stations. The ridge here is an asymmetric feature dropping steeply to Freen Deep in the south and much more gently to the deeper Peake Deep to the north. In the middle of the survey area the crest of the ridge is very nearly horizontal, remaining within 20 fathoms of 1,700 fathoms ( $3,110 \pm 34$  m) for about 7 km. Near the crest, particularly on the north side, are a series of nearly horizontal terraces not well shown on the map which range in width up to 2 km

Fig. 1. Index map showing the regional bathymetry constructed from the charts of Dr. A. S. Laughton, National Institute of Oceanography.

and in height of their downslope scarp to 100 m. They can often be followed for more than 5 km.

Table 1 summarizes the results of the dredge hauls. Glacial erratics were distinguished from rocks in place by a rounded or faceted shape, by the presence of striations, by comparison with rocks dredged from presumed erratic-free parts of the oceans and by the principle of homogeneity. This last criterion is that if a haul contains several rocks very similar to one another, though preferably not identical, then these rocks may be assumed not to be erratics<sup>2</sup>. Further discussion of the nature of the erratics and the principles on which they are distinguished will be published elsewhere.

More than 120 pieces of limestone (indurated ooze) were recovered in eight hauls. The pieces are soft, slightly lithified, can often be broken by hand, and their colour ranges from white to grey or light brown. The Upper Tertiary samples (mid-Miocene to Pliocene), recovered in dredge hauls intersecting the terraces near the crest of the ridge, contain a relatively high proportion of planktonic foraminifera and appear to have been winnowed during deposition, much of the fine material having been swept away. The Lower and Middle Tertiary samples

(lower Eocene to Oligocene), on the other hand, dredged from the lower slopes of the ridge, are typical pelagic oozes with a high proportion of fine-grained carbonate material. A core station (5971) on the border of Peake Deep beyond the north end of the detailed survey area also brought up this material.

Serpentinite was the principal hard rock recovered in all four dredge hauls that cut across the crest of the ridge, which thus appears to be a linear outcrop of serpentinite; it was also found in two dredge hauls on the southern slopes. The rocks are completely serpentized, but where secondary alteration is slight they can be seen to be the common pseudomorphs after harzburgites, with large bastite pseudomorphs after orthopyroxenes and little evident clinopyroxene.

The amphibolites show evidence of two stages of metamorphism. The first, of lower amphibolite facies, produced green hornblende-plagioclase rocks from basalts and dolerites; the igneous texture and some pyroxene phenocrysts are well preserved. Widely spaced fractures or coarse brecciation are the only signs of stress during this metamorphism. Many of the amphibolites show later retrograde metamorphism in which plagioclase is

Fig. 2. Bathymetric map of the area surveyed in detail and the surrounding ocean floor. The rectangular box outlines the detailed survey area. Depths are in uncorrected fathoms assuming a velocity of sound in water of 800 fathoms/sec. Contours within the detailed survey area are at 50 fathom intervals, outside at 100 fathom intervals. The abyssal plains of Peake Deep and Freen Deep are stippled. Dredge stations are shown, with the following symbols for the in place rocks recovered: ○, Upper Tertiary limestones; ●, Middle Tertiary limestones; ●, Lower Tertiary limestones; ▲, serpentinites; ◆, amphibolites; ■, gabbros; ■, basalts and dolerites. Core station 5971 is shown by a cross and the appropriate symbol.

replaced by zeolites and the rock is rather sheared and has lost its igneous texture. Potassium-argon ages date the first metamorphism at  $60 \pm 6 \times 10^6$  yr (the freshest amphibolite), and measurements of three retrograded amphibolites ( $29 \pm 2$ ,  $21 \pm 5$ ,  $27 \pm 4 \times 10^6$  yr) suggest a best estimate for the age of the zeolitization and shearing of  $26 \pm 4 \times 10^6$  yr.

Two hauls made close together near the foot of the southern slope contained blocks of olivine-hypersthene gabbro in which most of the olivine had been replaced by iron oxide. In the neighbourhood of joint planes cutting the rock the ferro-hornblende minerals have been entirely replaced by green hornblende, though the plagioclase is unaffected. Evidently the gabbro has suffered, though to a lesser degree, the same metamorphism that has produced the amphibolites. Fresh or slightly weathered basalt and dolerite fragments were found in one haul near the crest of the ridge and a more profoundly weathered specimen in a haul from the borders of Freen Deep.

Table 1. LOCATIONS AND CONTENTS OF DREDGE HAULS

Station	Position	Depth (fathoms)	Probable age range of limestones	Hard rocks
5607	42° 53-9' N 20° 11-8' W	1,700	—	Serpentinites*
5608	42° 52-1' N 20° 16-8' W	2,150- 2,350	Lower to middle Eocene	—
5610	42° 50-8' N 20° 16-8' W	2,800- 2,600	—	1 weathered basalt 2 amphibolites*
5619	42° 53-8' N 20° 16-6' W	1,750	Middle-upper Miocene or Pliocene	—
5628	42° 50-3' N 20° 12-2' W	2,750- 2,650	Lower or middle Eocene	1 serpentinite
5669	42° 55-0' N 20° 11-5' W	1,800- 1,900	Middle or upper Eocene and Miocene or Pliocene	—
5675	42° 54-2' N 20° 12-8' W	1,700	Upper Tertiary (smear on serpentinite)	Serpentinites with carbonate veins
5676	42° 53-6' N 20° 15-7' W	1,700	—	One serpentinite breccia
5677	42° 54-2' N 20° 15-9' W	1,750	Upper Miocene or Pliocene	—
5678	42° 54-6' N 20° 11-2' W	1,850	—	Basalt, dolerite, serpentinite*
5679	42° 50-7' N 20° 16-2' W	2,800- 2,500	—	More or less unalitized gabbro*
5681	42° 51-5' N 20° 16-5' W	2,500	Lower or middle Eocene	More or less unalitized gabbro
5683	42° 54-4' N 20° 13-4' W	1,700	Middle to upper Miocene or Pliocene	Serpentinites*
5685	42° 52-0' N 20° 12-4' W	2,550- 2,250	Oligocene or lower Miocene	Amphibolites, serpentinites

\* Denotes hauls including glacial erratics.

Basement rocks (serpentinites, amphibolites and gabbros) and unmetamorphosed Lower to Middle Tertiary limestones were recovered together in four different hauls; this association suggests a depositional rather than an intrusive relationship. The formation of the basement and its exposure at the ocean floor must thus be earlier than the lower Eocene ( $50 \times 10^6$  yr) and this is confirmed by the age of  $60 \pm 6 \times 10^6$  yr of the freshest amphibolite.

Metamorphism at the lower amphibolite facies appears to require temperatures of about  $350^\circ\text{C}$ . Such temperatures are only reached well within the mantle beneath oceanic regions of normal heat flow ( $1.3 \times 10^{-6}$  cal  $\text{cm}^{-2}$   $\text{sec}^{-1}$ ), and the temperature at the base of normal oceanic crust can be calculated to be about  $200^\circ\text{C}$ . In regions of high heat flow (about  $6 \times 10^{-6}$  cal  $\text{cm}^{-2}$   $\text{sec}^{-1}$ ) the necessary temperatures can be reached at depths about 3 km or less beneath the ocean floor. Even at these shallow depths considerable tectonic activity is necessary (in the absence of erosion on the ocean floor) to expose amphibolites on the surface. The presence of basic igneous rocks indicates that the basement also formed in a region of igneous activity. These three requirements for the formation of the basement, high heat flow, tectonic activity and igneous activity, are met nowadays only at the crests of mid-ocean ridges, and it is suggested that when the basement was being formed this area was at the crest of the mid-Atlantic Ridge.

This complex basement, rather similar to that found at the crests of mid-ocean ridges today<sup>3,4</sup> (and probably

showing a similar topographic roughness), was then gradually covered with normal pelagic ooze from the lower Eocene (and probably from earlier times in local depressions that the dredge did not sample) to the Oligocene, and would probably have appeared a typical area of ocean bed.

The next event in the geological development of the region appears to have been the opening of the Kings Trough feature. This event can be dated by two concordant lines of evidence. First, the amphibolites affected by zeolitization and shearing, a phenomenon that seems to require a definite rise in temperature or increase in activity of circulating water, show K-Ar ages that converge at about  $26 \times 10^6$  yr, suggesting a geological event at this time. Second, the transition from normal pelagic to winnowed sediments which occurred in about lower Miocene times (dated at about the same age<sup>5</sup>), indicates that after that time sediments were deposited on a local topographic high, whereas before they were formed by normal accumulation on the ocean floor. Such a change in conditions could be brought about by the elevation of Palmer Ridge. The formation of the Kings Trough feature, or at least this part of it, can thus be dated with fair certainty at about  $26 \times 10^6$  yr.

After the formation of this feature pelagic ooze continued to accumulate through the Miocene and Pliocene on benches near the crest of the ridge, being somewhat winnowed as it was laid down, and formed the flat-topped terraces visible today. Seismic profiler records of a traverse across the ridge show such a wedge of sediment perched high up near the crest and containing horizontal layering (E. J. W. Jones, personal communication).

There remains the question of how the ridge was uplifted. The long narrow crest seems to be a continuous outcrop of serpentinite and may mark the axis of a long serpentinite intrusion which, at least at this place, has broken through the overlying rocks to form a level spine. Such intrusions of serpentinite are well documented from regions of recent folding<sup>6</sup>. It is suggested that this intrusion has tilted up the rocks on each side to form a broadly anticlinal structure, so that the pre-existent sediments now dip away from the crest down the flanks of the ridge. This would explain the frequent sampling of Lower Tertiary material from many different depths on the north and south slopes.

Table 2 summarizes the postulated geological evolution of this area.

Table 2

Date	Event
About $60 \times 10^6$ yr	Formation of complex igneous and metamorphic basement at the then mid-Atlantic ridge crest.
$60-26 \times 10^6$ yr	Normal pelagic sedimentation
About $26 \times 10^6$ yr	Uplift of Palmer Ridge accompanied by serpentinite intrusion
$26-0 \times 10^6$ yr	Accumulation of winnowed sediments near the crest of Palmer Ridge.

It was indicated here that the basement in this region must have been formed, on a uniformitarian hypothesis, at the crest of the mid-ocean ridge. Palmer Ridge is now 650 km from the ridge axis and has presumably been moved there by a process of ocean floor spreading. Other evidence exists to support the hypothesis of ocean floor spreading<sup>7-10</sup>, which now has a reputable standing. On the basis of the radiometric date of the freshest amphibolite and the age of the earliest sediments found, an average rate of spreading on one side of the ridge (half the rate of ocean opening) of from  $10-13$  km/ $10^6$  yr ( $1.0-1.3$  cm/yr) may be deduced for this part of the ocean over the past  $60 \times 10^6$  yr. These figures fall comfortably within the range of rates ( $0-1.75$  cm/yr) suggested by previous authors for comparable oceanic regions<sup>3,8,9,11,12</sup>.

We thank for assistance, advice and criticism the late Dr. M. N. Hill, Dr. A. S. Laughton, Dr. D. H. Matthews and all other scientists taking part in the two cruises of R.R.S. *Discovery*, and her officers and crew for their invaluable

assistance. We also thank Mr. J. Mitchell and Dr. R. Grasty for determining the radiometric ages.

## Major Volcano-Tectonic Lineament in the Ethiopian Rift System

by

P. A. MOHR

Geophysical Observatory,  
P.O. Box 399,  
Addis Ababa, Ethiopia

Possible transform faults which offset the Wonji fault belt can be traced into lines of weakness dating back to the Jurassic in the surrounding Somalian and Ethiopian plateaux. This makes it unlikely that the Afar depression was produced by tensional separation during the formation of the Red Sea Rift.

THE preparation of a detailed 1:500,000 tectonic map and 1:1 million volcanological map of the Ethiopian Rift System, including Afar, for the UMC Subcommittee on African Rifts has revealed at once the complexity of this Rift System and yet its few dominating tectonic features.

The Main Ethiopian Rift, which extends from the Margherita-Chamo basin north-north-eastwards past Addis Ababa where it begins to funnel out into the Afar depression, is characterized by a peculiar, narrow belt of intense recent faulting. This has been termed the Wonji fault belt<sup>1</sup>, and all active and recent volcanicity along the Main Ethiopian Rift is situated on this belt. The fault belt does not follow the median axis of the Rift floor precisely (Fig. 1). It suffers several dextral transverse displacements along the Rift, particularly along the Chilalo-Guraghe line (X-X' on Fig. 1) and the Yerer-Gugu line (Y-Y' on Fig. 1). The Chilalo-Guraghe displacement coincides with the highest elevation of the Rift floor at the Awash-Maki watershed and is marked by severe gravity anomalies<sup>2</sup>, while the Yerer-Gugu line is responsible for the Rift embayment at Addis Ababa. Thus, although the Rift east of Addis Ababa seems to have a S.W.-N.E. orientation, the faulting of the Wonji fault belt remains S.S.W.-N.N.E. but with several dextral displacements, each of which is associated with a strong lineament crossing the Rift.

The Wonji fault belt was originally mapped northwards as far as the volcano Fant-ale<sup>1</sup>. Until the present work the continuation of the belt into Afar was a matter for speculation, though many years previously Dainelli<sup>3</sup> had made note of an alignment of volcanic centres north-eastwards from Fant-ale to Mussa-ali. The new mapping shows that the fault belt and its associated alkaline silicic volcanic centres continue north-north-eastwards from Fant-ale to the region immediately west of Lake Abbe, with a large dextral displacement along the Ajelu-Amoissa line (Z-Z' in Fig. 1). Between Fant-ale and Lake Abbe the Wonji fault belt widens in places to 40 km, but the volcanic centres lie on or close to the western margin of the belt.

Immediately north of Lake Abbe the fault belt turns abruptly almost northwards but is to a large extent obliterated by intense faulting which trends W.N.W.-E.S.E. and N.W.-S.E. and extends from the Gulf of Tadjura, curving round towards the Salt Plain. This faulting has produced local horsts and rift valleys, and some of the latter are associated with monoclinical warping.

It seems likely that the active Erta-ale basaltic volcanic chain, lying farther north-west within the Salt Plain, is associated with N.W.-S.E. monoclinical warping.

The N.-S. to N.N.E.-S.S.W. faulting of the Wonji belt reappears strongly north of latitude 12° N., although

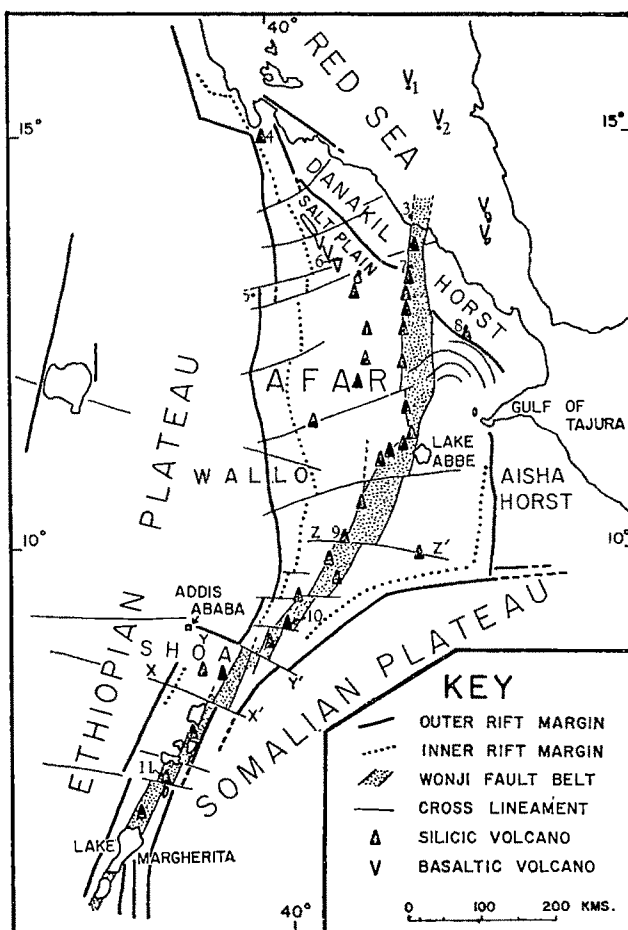

Fig. 1. Some important volcanic and tectonic lineaments in the Ethiopian Rift System. X-X' is the Chilalo-Guraghe line, Y-Y' is the Yerer-Gugu line, Z-Z' is the Ajelu-Amoissa line. 1, Jebel Teir; 2, Jebel Zebair; 3, Kod Ali; 4, Alid; 5, Amba Alaji; 6, Erta-ale; 7, Dubbi; 8, Mussa-ali; 9, Amoissa; 10, Fant-ale; 11, Chabbi.

it is complex in form. The direct alignment reappears at the site of a narrow belt of semicircular faulting of about 30–40 km radius. Preliminary evidence suggests that this pattern represents not subsidence or uplift but the results of clockwise rotation. Whatever the cause of this feature, the Wonji fault belt proceeds northwards from the west margin of the semicircle and forms an intense volcano-tectonic lineament in the Dubbi region of the Danakil Horst. This strong meridional lineament forms an abrupt south-eastern limit to the Salt Plain, and strikes directly across the Danakil Horst. The Danakil Horst is composed of Pre-Cambrian, Mesozoic and Lower Tertiary rocks like those of the Ethiopian and Somalian Plateaux but structurally more deformed. This block of ancient rocks is obliquely traversed by the continuation of the Wonji fault belt, and is covered with recent volcanic effluvia, both silicic and basaltic. The three Dubbi volcanoes with their huge calderas lie close to the western margin of the fault belt.

A northward prolongation of the fault belt into the Red Sea coincides initially and on its western margin with the peridotitic island of Kod Ali. To the N.N.E. the belt heads towards the volcanic islands of Jebel Teir and Jebel Zebair.

The Wonji fault belt is marked by dormant alkaline silicic volcanic centres. Many of the volcanoes have a simple or compound caldera, and have been sources of extensive ignimbritic flows in late Tertiary or Pleistocene times. In Holocene times flood basalts have emerged from fissures along this line.

The existence of this major volcano-tectonic line in Ethiopia is relevant to theories on the origin of the Afar depression and its relation to the Red Sea. The manner in which it cuts straight across structures of Red Sea trend is immediately evident, and if the Wonji fault belt is postulated to be a proto-development of the tensional central trough of the Red Sea<sup>3</sup> its discordance with this trough suggests that Afar structurally belongs first to the African Rift System and only secondarily to the Red Sea System. Some evidence also comes from the new 1:500,000 tectonic map. The gravity-geology surveys of Afar—published<sup>2,4</sup> and unpublished—suggest that the tectonic margin of the Red Sea trough south of latitude 15° N. is formed by the eastern margin of the Danakil Horst rather than the Afar-Ethiopian Plateau margin. Two other features which emerge from the new tectonic map suggest that the Afar area has persisted as a structural unit, contrary to some ideas of the proponents of continental drift. First, the Basement Mesozoic and Triassic rocks of the Ethiopian Plateau extend for a considerable distance eastwards into Afar, where they thicken and disappear below lavas and sediments (Desset Series) of the Afar floor. The distance between what has been termed<sup>3,6</sup> the inner and outer structural margins of western Afar reaches nearly 100 km in Wallo and north

Shoa (Fig. 1), a width wholly formed of downwarped old rocks. The extraordinary marginal graben of Afar<sup>4,6</sup> lie at the outer structural margin. The position of the inner structural margin of Afar is such that, if the Danakil Horst and the Aisha Horst are also taken into account there is insufficient space available for a reconstruction which superimposes south-western Arabia on Afar. Second, northern and western Afar are characterized, not only by the generally N.N.W.–S.S.E. oriented belts of intense, short curvilinear faulting, but also by long straight faults trending E.N.E.–W.S.W. No vertical displacements are present along these lines, some of which cut directly from the eastern Ethiopian Plateau, across Afar and over the Danakil Horst. From preliminary field-work I have tentatively identified these lineaments with approximately E.–W. tectonic lines on the Ethiopian Plateau, some of which (for example, Amba Alaji)<sup>4</sup> are known to have been active in the Jurassic. There is similar evidence from the deformed Mesozoic strata of the Danakil Horst. If the history of these lineaments extends back to the Mesozoic and their linearity is still extant, it would seem that the position of the Danakil Horst in relation to the Ethiopian Plateau has not altered during that time. The thickening and coarsening of the Mesozoic rocks towards the Salt Plain, both eastwards from the Ethiopian Plateau and westwards from the Danakil Horst, suggest that the Afar region was a subsiding basin of deposition from this early time. There is, therefore, no evidence of any tensional separation in Afar which has been produced by the formation of the Red Sea rift.

The importance of approximately E.–W. lineaments crossing the Ethiopian Rift System has only recently been recognized. Displacements both of the marginal rift faulting and of the Wonji fault belt occur along these lines. Although the faults are straight and extensive, no evidence of true transcurrent displacements along any of them has yet been recognized. Tentatively, therefore, it is considered that the E.–W. lineaments mark transform faults extending under the whole of the Ethiopian Swell, which are most strongly manifested superficially at the margins and within the Rift System.

The refinement of previous gravity data<sup>2,4</sup> has revealed that the regional Bouguer gradient over the northern Ethiopian Plateau has a strike of E.N.E.–W.S.W. This is precisely the direction of important lineaments in Afar, and is perpendicular to the Red Sea axis but also close to the Gulf of Aden trend.

## Removing Viruses from Water by Polyelectrolytes

by  
J. H. JOHNSON  
J. E. FIELDS  
W. A. DARLINGTON

Monsanto Company, St. Louis, Missouri

Polymers based on divinylbenzene-crosslinked styrene/maleic anhydride copolymer can adsorb 100 per cent tobacco mosaic virus and more than 99.99 per cent polio virus from aqueous suspensions. The technique may be useful for preparing potable water by removing viral infectivity which may survive conventional treatment. It may also be useful in detecting viral contamination.

THE contamination of effluent and drinking waters by viruses is a problem of increasing importance to public health<sup>1–4</sup>. Current procedures for treating water are considered to be inadequate for the elimination of danger in times of maximum contamination<sup>5,6</sup>. New approaches

to the effective removal of virus and/or bacteria have therefore been sought as a means of producing potable waters from contaminated effluent. Concentration of several types of virus from sera and contaminated sewage effluent using various ion-exchange resins has already been reported<sup>7,8</sup>.

\* Polymer No. 7, 325 mesh; TMV/polymer ratio, 1-84; shaken 1 h.

Table 3. TMV ADSORPTION IN HANKS SOLUTION

Polymer No.	Virus adsorption (per cent)*	
	Water	Hanks solution
(3)	9	70
(6)	75	95
(7)	97	98

\* 1 mg polymer (325 mesh) in 4 ml. of Hanks solution; shaken 1 h; TMV/polymer ratio, 1:84.

Because the polio experiments were planned in Hanks physiological saline solution, the adsorption of TMV in Hanks solution was determined (Table 3) and found to be better than that obtained with controls free of inorganic ions.

Adaptation of the technique to studies of animal viruses introduces contamination by foreign protein as a factor in adsorption. Quaternized 100 per cent imide was evaluated for the removal of bovine serum albumin (BSA) at various ratios of BSA to polymer (Table 4). One milligram of polymer removed 90 per cent of 5–10 mg quantities of BSA. The efficiency of removal dropped at both high and low concentrations of protein.

Table 4. REMOVAL OF BSA FROM AQUEOUS MEDIA

BSA (mg/5 ml.)	Percentage of removal*		
	1	2	Average
0.5	62	68	65
1.0	70	74	72
2.0	80	80	80
5.0	91	90	90.5
10.0	90	93	91.5
25.0	—	48	48

\* 1 mg of polymer No. 7 (325 mesh) shaken with BSA solution for 1 h, filtered and BSA content of filtrate determined with Folin reagent using a standard curve prepared for BSA.

The performance in mixtures of TMV and BSA was evaluated using the standard contacting procedure. The polymer-treated virus-BSA filtrate was compared in an analytical ultracentrifuge with a TMV control (no polymer or BSA). Removal of 80–90 per cent of the TMV was achieved. Analysis of the filtrate with Folin reagent showed that 90 per cent of the BSA was still present, which indicated a selective removal of TMV from a solution containing twenty times as much BSA.

Sterilization was not required in the TMV screen, but was customary in experiments on polio virus. Autoclaving polymer suspensions at about 120° C for 20 min could chemically and/or physically alter the polymers so as to affect virus adsorption. Samples of polymers (3), (6) and (7) were autoclaved and the infra-red spectra of the products were compared with those of the originals. The results indicated no significant hydrolysis of amides or imides and no changes in the content of quaternary salt.

Autoclaving aqueous suspensions of 66 per cent imide and 100 per cent imide destroyed their ability to adsorb TMV virus but still permitted good adsorption with 100 per cent imide-methiodide (Table 5). Autoclaving in Hanks solution, however, substantially reduced the latter adsorption.

Table 5. EFFECT OF AUTOCLAVING POLYMER SUSPENSIONS

Polymer No.	TMV adsorption (per cent)*		
	Control†	In water	In Hanks solution
(3)	86	1	0
(6)	90	3	16
(7)	95	97	43

\* 1 mg polymer (325 mesh) in 4 ml. of water of Hanks solution, autoclaved for 20 min at 120° C. Virus added to cooled solutions, shaken 1 h, filtered and virus content of filtrate assayed.

† Hanks solution (no autoclaving).

Visual observations and ultramicroscopic studies indicated that the polymers became more dense, with numbers (3) and (6) actually forming films. The 100 per cent imide-methiodide became denser and more particulate. Autoclaving thus destroyed polymeric surfaces available for

virus adsorption, probably by fusing individual polymer particles.

When investigations of the adsorption of polio virus were carried out, care was taken to avoid autoclaved adsorbent and salinity. Selected polymers were evaluated for their adsorption of polio virus by the procedure previously outlined (Table 6). Addition of polymers (3) and (6) reduced polio virus titre in final filtrates by more than 99.9–99.99 per cent. This contrasts with the lesser adsorption (99.2 per cent) of polio virus found for polyanionic maleic copolymer<sup>11</sup> using twenty-five times as much polymer relative to cationic systems. No significant reduction occurred in the presence of the 'Amberlite XE-119' control. Polymer (7) formed a viscous virus-polymer complex gel which, in this experiment, could not be separated to yield a clear aqueous phase. Meaningful values could not be obtained.

Table 6. REMOVAL OF POLIO VIRUS

Treatment	P.F.U./0.5 ml.*	Virus removal (per cent)
Control	$0.8 \times 10^8$	
Polymer No. (3)	$< 0.5 \times 10^8$	> 99.9
Polymer No. (6)	$< 0.5 \times 10^8$	> 99.9–99.99†
'Amberlite XE-119'	$0.8 \times 10^8$	0

\* Average of the two plate counts for the dilution giving discrete plaques.

† At the minimum dilution tested no plaque-forming units (P.F.U.) were observed.

This experiment does not distinguish between loss of virus activity due to adsorption by the polymer and possible inactivation in the presence of polymer. Published results indicate, however, that viable virus can be eluted from several ion-exchange resin-virus complexes. It is probable that this is so in these experiments on polio virus. Furthermore, it does not establish the minimal ratios of polymer to virus required for the complete removal of virus.

It is shown that these cationic polyelectrolyte derivatives are excellent adsorbents of plant and animal viruses from dilute aqueous suspensions. The ease and strength with which a virus or proteinaceous material is adsorbed to surfaces are related to several parameters. In the case of the adsorption of negatively charged viruses by anion-exchange resins or polybases, the results indicate that the availability of surface area for adsorption is an important factor. Polymers prepared by solvent-non-solvent techniques increase the area by a factor of about ten (that is, from 4 to 40 m<sup>2</sup>/g as measured by the Brunauer-Emmett-Teller method) when compared with the ion-exchange control. A potential hundred-fold increase in area has been shown to be possible in the case of uncollapsed films cast from solvents<sup>14</sup>. Such films cast from appropriate functional polymers represent a promising approach to commercialization with filter mat types of equipment. Differences in performance were also noted for different functional groups and for varying charge density of the adsorbent. Other parameters for future investigation include: (1) hydrophilic-hydrophobic ratio, (2) the degrees, type and extent of ionization, (3) charge distribution, and (4) influences imparted by interactions with neighbouring group. This technology should make possible the removal of viruses and bacteria which survive standard treatment of contaminated effluent waters.

# Design of the Bronchial Tree

by

THEODORE A. WILSON

Department of Aeronautics and  
Engineering Mechanics,  
University of Minnesota,  
Minneapolis, Minnesota

The bronchial tree is so designed that the functions of the lung can be carried out with minimum entropy production.

A QUANTITATIVE description of some aspects of the architecture of the human lung has been provided by Weibel and Gomez<sup>1</sup>. One of the parameters which is described in their paper is the diameter of the tubes in the bronchial tree. They find that the average diameter  $d_z$  of the tubes after the  $z$ th bifurcation of the network is given by the expression,  $d_z = d_0 2^{-z/3}$ , where  $d_0$  is the diameter of the trachea. This is, of course, a simplified description of the system. Even if the model of a network of succeeding bifurcations in which the tubes of each generation can be assigned a common description is proper, there is, at least, a large variation of the properties of the  $z$ th generation about the average<sup>2</sup>. It does, however, seem to be a reasonable first step in the complete description of the passages of the lung and the form of this result is especially convenient for analysis.

The purpose of this article is to show that the value of tube diameter as a function of the location of the tube in the bronchial tree as reported by Weibel and Gomez is the same as the value for which gas of a given composition can be provided to the alveoli with minimum metabolism or entropy production in the respiratory musculature. The hypothesis that the characteristics of the design of biological systems take values for which a given function can be accomplished with minimum total entropy production has been tested previously in a description of ventilation as a function of total oxygen consumption and a description of capillary spacing in muscle tissue as a function of oxygen consumption in the muscle<sup>3,4</sup>.

In the application of the hypothesis to the description of the bronchial tree, the diameter of the tubes in the  $z$ th generation of the network is imagined to be variable while all other parameters of the respiratory system and the function of the respiratory system are held constant. It is assumed that the function of the tubes is to conduct gas between the atmosphere and the alveoli so that the alveolar oxygen and carbon dioxide tensions are held at given values. For a given oxygen consumption this requires that the alveolar ventilation  $\dot{V}_A$  must have a given value. The total ventilation  $\dot{V}$  is a function of the tube diameters since the dead space, which is the total volume of the bronchial tree, must be filled at each inspiration. The total ventilation  $\dot{V}$  is given by equation (1).

$$\dot{V} = \dot{V}_A + v \frac{\pi}{4} \sum_z d_z^2 l_z 2^z \quad (1)$$

In equation (1),  $v$  is the breathing frequency and  $l_z$  is the length of the tubes in the  $z$ th generation.

Another variable which depends on the geometry of the duct is the pressure drop between the atmosphere and the alveoli. For Poiseuille flow in a circular tube, the pressure drop across the  $z$ th generation of tubes  $(\Delta p)_z$  is given by equation (2).

$$(\Delta p)_z = \frac{128 \mu Q_z l_z}{\pi d_z^4} \quad (2)$$

In equation (2),  $Q_z$  is the rate of volume flow through a single tube in the  $z$ th generation and  $\mu$  is the coefficient of viscosity for air. The value of  $Q_z$  is approximately  $\dot{V}/2^z$ . The assumption that the flow is fully developed gives a lower limit for the estimate of  $(\Delta p)_z$ . The appro-

priate dimensionless number (Reynolds number)  $\times (d_z/l_z)$  has large enough values for the first few generations that the pressure drop cannot be taken to be independent of the entrance conditions<sup>5</sup>. If, however, we use an estimate for an upper limit for  $(\Delta p)_z$  corresponding to a flat velocity profile at the inlet, then the value of the diameter of the trachea would be increased by only 25 per cent over the value calculated below and the effect on the values of the diameters of the tubes of succeeding generations would quickly become negligible.

Since the alveolar ventilation is held fixed, independent of tube radii, the entropy production in the mixing of alveolar gas with air is fixed, independent of the radii of the tubes. The main entropy sources which depend on the tube radii are the viscous dissipation in the gas flow and the chemical and mechanical dissipation in the respiratory muscles. Because all the energy released in the chemical reactions in the muscles is eventually dissipated into heat, either within the muscle or in the gas flow and structural motion driven by the muscle, a good estimate of the total entropy production  $\dot{S}$  is given by the total energy released divided by the temperature.

$$\dot{S} = H \dot{V} \dot{O}_2 / T \quad (3)$$

In equation (3),  $H = 5$  cal/ml., the energy released per ml. of oxygen burned in the respiratory muscles,  $\dot{V} \dot{O}_2$  is the oxygen consumption of the respiratory musculature in ml./min and  $T = 300^\circ$  K. In the entropy balance for this process, the difference in entropy between the reactants and products of the chemical reaction is negligible compared with the heat flux.

We seek the value of  $d_z$  for which  $\dot{S}$  is a minimum. At this value,  $d\dot{S}/dd_z = 0$ . The main contributions to

Fig. 1. The diameter of the tubes in the bronchial tree plotted on a logarithmic scale as a function of the location of the tube in the bronchial tree. —, Tube diameter for minimum entropy production;  $\circ$ , data of Weibel and Gomez.

the derivative are assumed to be due to the dependence of the total ventilation on  $d_z$  and the dependence of the pressure drop on  $d_z$ . The value of  $d_z$  which satisfies the design hypothesis is given by the value of  $d_z$  which satisfies equation (4).

$$\frac{dS}{dd_z} = \frac{H}{T} \left( \frac{\partial \dot{V}_{O_2}}{\partial \dot{V}} \frac{\partial \dot{V}}{\partial d_z} + \frac{\partial \dot{V}_{O_2}}{\partial (\Delta p)} \frac{\partial (\Delta p)}{\partial d_z} \right) = 0 \quad (4)$$

This equation is a quantitative expression of the idea that the tube diameter is limited at small values by the increasing flow resistance with decreasing tube diameter and is limited at large values by the increasing tube volume and dead space with increasing tube diameter.

It follows from equation (1) that  $\partial \dot{V} / \partial d_z = \frac{\pi}{2} v d_z l_z 2^z$  and from equation (2) that  $\partial (\Delta p) / \partial d_z = -512 \mu \dot{V} l_z / \pi d_z^5 2^z$ . Substituting these values in equation (4) and solving for  $d_z$  results in equation (5).

$$d_z = \left[ \left( \frac{1024 \mu V}{\pi^2 v} \right) \left( \frac{\partial \dot{V}_{O_2}}{\partial (\Delta p)} / \frac{\partial \dot{V}_{O_2}}{\partial \dot{V}} \right) \right]^{\frac{1}{3}} 2^{-z/3} \quad (5)$$

The coefficient in the relation can now be evaluated using the following values of the parameters:  $\mu = 1.8 \times 10^{-4}$  poise,  $v = 15$  breaths/min, and  $\dot{V} = 30$  l./min, a value in the middle of the range for this parameter. The values of the physiological parameters  $\partial \dot{V}_{O_2} / \partial \dot{V}$  and  $\partial \dot{V}_{O_2} / \partial (\Delta p)$  have been measured by Campbell, Westlake, and Cher-

niack<sup>6</sup>. They find that  $\partial \dot{V}_{O_2} / \partial \dot{V} = 0.25$  ml./l. over the range of ventilation up to 40 l./min. They also find that the differential efficiency of maintaining the same ventilation with increasing flow resistance is 10 per cent so that  $H(\partial \dot{V}_{O_2} / \partial (\Delta p)) = 10 \dot{V}$ . Then  $d_0 = 1.25$  cm and the value of  $d_z$  as calculated from the hypothesis is given by equation (6).

$$d_z = 1.25 \times 2^{-z/3} \text{ cm} \quad (6)$$

The curve represented by equation (6) is plotted in Fig. 1 along with the data of Weibel and Gomez.

The values of the diameters of the tubes making up the bronchial tree which have been calculated from the hypothesis agree with the values observed by Weibel and Gomez. It can be said, therefore, that the diameters of the conductive air passages of the lung are those for which a given alveolar ventilation can be maintained with minimum entropy production.

I thank Jack Saari and Larry Keen for assistance in this research. This work was supported by a grant from the U.S. Public Health Service.

## Origin of Genetic Variability: Combinations of Peroxidase Isozymes determine Multiple Allelism of the S Gene

by

K. K. PANDEY

Grasslands Division, Department of Scientific and Industrial Research, Palmerston North, New Zealand

Electrophoresis suggests that peroxidase enzymes are involved in the expression of the S alleles which control incompatibility. This may be linked with the mechanism of action and the origin of S genes and thus with the origin of large scale variability.

FROM the evolutionary point of view a virtually unlimited variability at the level of the organism is advantageous, and this is made possible in nature through the evolution of sex. The key to this virtually inexhaustible potential lies in "recombination" at several levels of organization<sup>1-4</sup>. Looking at evolution as a whole, one principle seems to stand out as being consistent with evolution at all levels. Large-scale variation tends to be created by multiple combinations of a minimum number of suitably adaptive existing elements, rather than by the creation of new genetic elements *per se*.

Enzyme (protein) molecules, the many hundreds of forms of which catalyse all the reactions of living matter, are composed of one or more polypeptide chains, each the product of a single gene. All these molecules are composed of differing arrangements of twenty amino-acids, which are coded by the DNA molecule using non-overlapping triplet combinations of only four nucleotide bases<sup>5-7</sup>. All developmental and differentiations patterns appear to be produced by large-scale variation in the control, by combinations of regulator genes, of a comparatively small fixed number of elements—the structural genes. Finally, on the population level, a few thousand genes through recombination produce billions of individuals all different from each other. In this scheme of the origin of variation there is, however, one obvious gap: how does a large-scale neomorphic (equivalent) variation arise in the same gene?

*Origin of multiple S alleles.* S alleles controlling incompatibility behaviour in plants are an extreme example of

neomorphic variation. In species which have been tested approximately 80 per cent of the total number of alleles tested were found to be different. For example, Williams<sup>8</sup> in his work with red clover found seventy-eight different alleles out of a possible maximum of eighty-eight in forty-four plants tested. Thus, there appears to be no limit to the number of alleles. As far as the author is aware no neomorphic variability of a gene on such a scale is known in any other genetic system in any organism.

In the extensive genetic investigation of the S complex<sup>9-21</sup> no evidence is available to suggest that the large number of alleles has arisen through recombination between a relatively small number of genetic elements controlling the specificity of the S gene. Superficially it would seem that the extreme variability at the S locus defies the principle stated here. Here seemingly the same genetic element has assumed innumerable forms. The resolution of this dilemma depends on the understanding of the molecular basis of this variation.

Isozymes<sup>22</sup>, different molecular forms of the same enzyme, have been demonstrated by electrophoretic techniques in a large number of organisms. Different isozymes of the same protein have been shown in plants and animals to be implicated in normal growth and differentiation as well as in abnormality and disease<sup>23-25</sup>. The occurrence of isozymes has been shown to be controlled by a particular gene in only a very few cases. So far the most elaborate investigation of this type in higher plants has been made by Schwartz<sup>26</sup>, who investigated the origin of esterase isozymes in maize endosperm. No genetic

Fig. 1. Peroxidase isozymes in different *S* allelic styles. Different plants having the same *S* genotype show an identical electrophoretic pattern.

system in plants controlling multiple isozymes specified by the same gene has yet been investigated.

**Peroxidase isozymes in different *S* allelic styles.** Genetic<sup>9-21</sup>, immunogenetic<sup>27</sup> and biochemical<sup>28</sup> investigations of incompatibility suggest that the *S* gene acts by producing specific proteins in the pollen and style, each allele giving rise to different specificity. In the present investigation, control of stylar enzymatic activity by the *S* locus was examined in *Nicotiana*. The enzyme peroxidase was specifically chosen for investigation because of its suggested involvement in the control of protein activity<sup>29</sup>.

The following genotypes, four homozygous and three heterozygous for *S* alleles, were examined (usually several plants in each genotype):  $S_1S_1$  (four),  $S_3S_3$  (two),  $S_{F10}S_{F10}$  (two) and  $S_{F11}S_{F11}$  (four);  $S_1S_{F11}$  (two),  $S_3S_{F11}$  (one) and  $S_{F10}S_{F11}$  (two). Out of seventeen plants examined nine were pure *N. alata* (self-incompatible) and eight were extracted from hybrids between *N. alata* and *N. langsdorffii* (self-compatible)<sup>9-21</sup>. The latter plants

varied greatly among themselves, and from the pure *N. alata*, in flower size, shape and colour.

Styles from emasculated mature flowers were collected and stored at  $-20^\circ\text{C}$  for 1-3 months. Extracts were prepared by grinding approximately 1 g of styles with a few drops of 0.05 molar *tris* hydrochloric acid buffer at pH 7.5. The slurry was centrifuged at 15,000*g* for 20 min and the supernatant was dialysed overnight against the same buffer. All treatment was done at  $3^\circ\text{C}$  to prevent denaturation. Enzyme components were separated by electrophoresis on acrylamide gel blocks prepared according to Tombs<sup>30</sup>. As many as six samples were run together in the same block in strictly comparable conditions. Electrophoresis was carried out for 3 h at about 20 m.amp, after which the gel was stained for 30-45 min in a specific stain for peroxidase (for stock reagent: to 1 l. of 7 per cent acetic acid add 160 g of sodium acetate, saturate with 1 per cent EDTA, filter, saturate with benzidine dihydrochloride, and filter again; hydrogen peroxide (1 ml.) is added to 100 ml. of stock reagent just before use).

The results showed that each allele had its own specific isozymic bands and that they were identical in all plants with the same allele irrespective of whether the plants were pure species or were of hybrid origin. Plants with two alleles invariably produced bands of both alleles (Fig. 1). There was a difference in intensity of various isozymic bands. Fig. 2 gives a diagrammatic sketch of bands of the seven genotypes investigated.

Two plants, 4820/29 and 4820/30, both of the same genotype ( $S_1S_{F11}$ ) and extracted from the same hybrid family, had each an identical extra band overlapping one of the usual bands ("e" in Fig. 1). The extra band was, however, brilliant purple in colour, in contrast to the blue of usual bands, and lay exactly on the top of the latter. The significance of this band is not clear.

The results suggest that (1) peroxidase isozymes determine *S* gene specificity and (2) the basis of allelism of this gene lies in the particular combinations of the specific isozymes. Although at this stage of the investigation the unlikely probability of the involvement of other enzymes in the determination of *S* specificity cannot be entirely ruled out, the present work reveals for the first

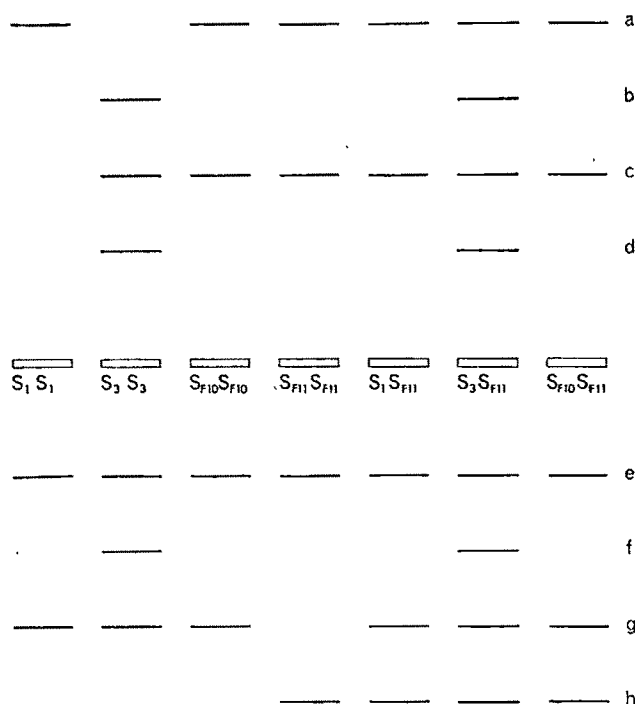

Fig. 2. Diagrammatic sketch of electrophoretic peroxidase isozymic patterns of seven *S* genotypes.

time a molecular basis of self-incompatibility, a widespread phenomenon in plants. In this context it is interesting to note that in the protozoan *Tetrahymena pyriformis* the multiple alleles of the mating type locus appear to control a number of esterase isozymes<sup>25</sup>, although in this case the picture is not so clear because the different isozymes controlled by the same allele do not appear at the same time. Further, the present work shows that at the gene level also, the basis of multiple variation is the same as at other levels, and therefore confirms the universality of the principle enunciated earlier, that large-scale variation in nature arises through recombinations of a comparatively few genetic elements rather than through creation of new genetic elements *per se*.

It is significant to find this principle so consistent throughout life, from the molecular level to the level of the highly complex multicellular organism. Apart from mathematical considerations, the necessity for such a principle seems obvious from another point of view: in the highly complex system of life processes the fewer the number of new unintegrated elements the fewer are the chances of error through interference at the molecular level<sup>21</sup>. So long as there is a built-in mechanism available to produce variation at all times, as there is in the DNA structure, a new variation can be incorporated when the system is ready and the circumstances favour it, and there is no need for the accumulation of entirely unintegrated new genetic elements. The very survival of the system depends on the elimination of redundancy.

**Mechanism of *S* gene action.** The discovery of the involvement of peroxidase in incompatibility enables us to take a fresh look at some of the still unresolved problems in this field. The two most important of these are concerned with (1) the physiological mechanism of *S* gene action, and (2) the nature of *S* gene mutations, natural and induced.

Peroxidase occurs very widely in plants<sup>22-24</sup>. It is known to be involved in the oxidative inactivation of certain biologically active proteins<sup>25</sup>, but the physiological significance of its activity in plants is not well understood. It is believed to participate directly, or through coupled oxidations, in various oxidative processes including respiration, lignification and degradation of auxin. In view of its very wide range of substrates<sup>22-24</sup> including certain proteins, amino-acids, hormones and enzymes, it probably plays a variety of parts in different physiological systems.

One of the physiological roles of peroxidase is its involvement in the destruction of the widely occurring growth promoting hormone indolyl-3-acetic acid (IAA). Evidence suggests that IAA, acting as inductor molecules, controls the activity of certain regulator genes involved in stem growth and flowering<sup>25,26</sup>. Thus the destruction of IAA would have the effect of repressing certain regulator genes which would otherwise be derepressed (activated) at that stage.

It is assumed here, with Lewis<sup>27</sup>, that the *S* gene complex produces an identical polypeptide molecule in pollen and style. This molecule is a dimer protein formed by polymerization of the identical primary molecules (monomers). In an incompatible pollination two identical dimers, one each from pollen and style, combine to form a tetramer with the aid of an allosteric molecule "which may be glucose, a protein or one of many small molecules". It is believed that only a tetramer is physiologically active in producing incompatibility; the dimers are inactive in this respect.

The present work suggests that the polypeptide molecule specified by the structural cistron of the *S* gene complex is peroxidase. It is proposed here that in an incompatible pollination the activated tetramer peroxidase destroys the growth promoting hormone IAA in the pollen tube. This destruction of the inductor molecule leads to repression of the regulator genes governing the production of growth substances for the pollen tube, thus

causing its inhibition. The activated peroxidase may further limit growth by blocking the pollen tube wall through the formation of a rigid lignin matrix in the membrane<sup>23,24</sup>, thus stopping the entrance of nutrients from the style to the pollen tube and probably also making it incapable of expansion. In a compatible pollination, where the dimers from the pollen and style are different, there is no such tetramerization. This allows the IAA to continue its derepression of the regulator genes, thus promoting pollen tube growth.

It is interesting to find that the peroxidase isozymes from plants with two different *S* alleles have only isozymes specified by each allele. No extra hybrid isozymes, having an intermediate electrophoretic mobility of parental isozymes, as reported by Schwartz<sup>28</sup>, are produced, thus providing a molecular basis for the lack of *S* allele interaction, so essential for the success of the gametophytic system of incompatibility.

**Mutation, and origin of new *S*<sub>I</sub> alleles.** The present work suggests that new self-incompatibility alleles generally arise by recombination of a small number of genetic elements specifying peroxidase isozymes. Each allelic specificity is determined by a unique combination of these isozymes. Changes in the constituent genetic elements of an *S* allele, giving rise to a new allelic specificity, may come about largely through loss, inactivation or suppression, or equal or unequal crossing over between the two homologous alleles, and rarely through a point mutation producing a new isozyme. Thus, only eight elements in the structural cistron could, through recombination, produce 255 alleles, assuming one element to be the minimum required for specifying an allele. The above hypothesis can explain the large number of self-incompatible alleles found in the natural population, but it does not explain by far the most puzzling feature of the results of work on the *S* gene, which is the inability in experimental conditions to obtain a single mutation from one self-incompatibility allele to another in intensive experiments<sup>5</sup> involving millions of pollen grains in *Oenothera*, *Prunus*, *Trifolium*, *Petunia* and *Nicotiana*. All induced mutations obtained so far were mutations in the regulator cistron producing self-compatibility; none was found in the structural cistron giving a new *S*<sub>I</sub> specificity. Nevertheless, the conclusion is that to account for such a large number of alleles in the population, the mutation rate must be high enough for the mutation to be normally detected in experimental conditions<sup>28,29</sup>. The fact that no such mutation has been identified leads me to the belief that there is a new aspect to the *S* gene mutation not yet illuminated by mutation studies.

Investigations of different forms of *S* alleles and their interactions in various breeding systems suggest that the activities of the *S* gene complex are an integral part of the physiology of reproduction including sporophytic as well as gametophytic phases of the life cycle. The role of *S* alleles in sexual mechanisms, including intra-specific and inter-specific, and homomorphic and heteromorphic, pollen-style incompatibility, is well known<sup>9-21</sup>. What is not so well known is that the action of certain elements of the *S* complex may be very early in the sporophytic phase, as is indicated by observations in *Theobroma* and *Trifolium* which show parallelism between interspecific hybridization and grafting<sup>40,41</sup>. The species or genotypes that were sexually compatible were also graft-compatible, and conversely, combinations that were sexually incompatible were also vegetatively incompatible.

These observations all point to one fact, that the genetic elements comprising the *S* gene complex have a very wide range of expression, certain elements being expressed very early in the sporophytic phase and others acting late in the gametophytic phase. There is evidence to suggest that IAA acts as an inductor (probably in conjunction with certain other hormones) to derepress certain elements of the *S* complex and some other genes governing

the reproductive phase<sup>35,36</sup>, long before the onset of flowering.

It is suggested here that the precursors of the substances determining the specificity of an *S* allele are already laid down in the cytoplasm early in the sporophytic phase, so that any mutation in the structural cistron occurring late in the life of the sporophyte or during the gametophytic phase is unable to express itself until the next sporophytic generation. This would mean that natural selection for *S* specificity mutation does not operate at the gametophytic level (basis of our mutation work), but only at the sporophytic level. This lag in the expression of *S* gene mutation might have required a comparatively high mutation rate, since it would be effective only through compatible pollinations, were it not that it is fully offset by the multiplication of each mutation many times over, through mitotic cell division, by the time it reaches the spore stage. This hypothesis, if correct, would explain our inability with present techniques to produce *S* specificity mutations, and at the same time account for the large number of *S* alleles occurring in nature.

A considerable gap between gene action and final expression of the phenotypic character appears to be a common feature of genes associated with reproduction<sup>42</sup> and phase variation<sup>43</sup>. The basis of monoecism, from algae to higher plants, is the mutually exclusive action of two sex determining genes which often act to fix the sex during early vegetative growth, although the observable sex differences are not manifested until later.

From these considerations it seems probable that the production of peroxidase isozymes is one of the last acts of the *S* gene complex, the earliest of which may be closer to seed germination than to microspore germination.

I thank Dr. L. Corkill, director, Grasslands Division, and Dr. G. W. Butler, director, Plant Chemistry Division, for facilities and encouragement. I also thank Dr. J. W. Lyttleton of the Plant Chemistry Division for his help in developing the electrophoretic technique, and Miss A. Laxton and Mrs. E. K. Hick for technical assistance.

## Influence of Temperature on Lizard Testes

by  
PAUL LICHT  
SANKAR L. BASU

Department of Zoology, University of California,  
Berkeley, California

SPECIES differences in thermal sensitivity are evident in numerous tissues and enzymes from lizards. These variations correlate well with differences in the preferred body temperatures of the species. (Preferred body temperatures are defined here as those temperatures maintained by lizards in thermal gradient chambers in which a wide range of temperatures is available. Temperatures maintained in such conditions are very similar to those maintained by animals active in nature<sup>1-4</sup>.) Thus, species appear to be physiologically adjusted to different temperatures commensurate with their thermal preferences. Evaluation of the extent of thermal divergence and the mechanisms involved therein is, however, limited, because the available data deal primarily with somatic functions. Reproductive tissues may not show similar relations to temperature. The male germinal epithelia of many plants and animals are generally considered to be less heat-

Incorporation of tritiated thymidine in organ culture shows that the temperature at which testicular cells begin to degenerate differs between two species of lizards. These differences parallel the differences in the preferred body temperature of the species.

resistant and less capable of adapting with respect to temperature than the somatic tissues<sup>5</sup>.

In lizards, exposures to body temperatures only slightly above preferred levels may cause testicular impairment and spermatogenic arrest<sup>6</sup>. Comparisons of the temperatures necessary to cause such impairment suggest some interspecific divergence in testicular heat-resistance. Interpretations of the effects of temperature *in vivo* are, however, hindered by concomitant systemic disorders, and it is not clear to what extent testicular damage results from the direct action of heat. To define better testicular heat-resistance and its relation to the preferred body temperatures of lizards, the thermal responses of testes from several species were compared *in vitro*.

Comparisons were based on two species of lizards with distinct thermal preferences: the American chameleon, *Anolis carolinensis*, from Louisiana, and the desert sand

Fig. 1. The effects of temperature on testicular explants from a single *Uma scoparia*. (A) Tissue control stained with haematoxylin and eosin before cultivation; (B) autoradiograph, stained with haematoxylin, of tissue labelled with thymidine for 10 h and then cultured at 37° C for 5 days; (C) autoradiograph of explant labelled with thymidine and cultured at 40° C for 5 days. All tissues were fixed in Bouin, embedded in paraffin, and sectioned at 4µ.

lizard, *Uma scoparia*, from southern California. When provided with a wide choice of temperatures, the *Uma* maintain body temperatures between 34° C and 40° C, with an average of 37.5° C, whereas the *Anolis* regulate between 28° C and 36° C, with an average of 32.5° C (ref. 7).

Testes were divided into small explants, about 1–2 mm<sup>2</sup>. Each explant was cultured separately in 1 ml. of Waymouth's chemically defined medium (MB/752/1), using Chen's<sup>8</sup> modification of the watch glass method. Duplicate tests were made with Waymouth's medium supplemented with 5, 25, 50, or 100γ each of FSH and LH (follicle stimulating hormone, lyophilized porcine; and leuteinizing hormone, lyophilized equine), but these had little effect on the testicular cultures. Tissues were cultured for 3 and 5 days at various temperatures between 28° C and 44° C ( $\pm 0.2^\circ$  C) in a humidified atmosphere of 95 per cent oxygen and 5 per cent carbon dioxide. At the beginning of cultivation at each temperature, two explants from an individual were incubated for 10 h with 10–20 µc. of thymidine-methyl-<sup>3</sup>H (specific activity, 6.7 c./mmole). Another explant was incubated with the thymidine during the last 2 days of a 5 day cultivation. The viability and extent of differentiation of tissues were evaluated by the presence and localization of thymidine labelling and by comparing their general histological appearance with that of control tissues fixed before cultivation.

The effects of temperature on the testes of the two species are compared in Table 1. Maintenance of the germinal epithelium was best at the lowermost temperature used, 28° C, but there was little change or thymidine incorporation in these tissues. At intermediate temperatures, 32° C for *Anolis* and 37° C for *Uma*, thymidine incorporation was greatly enhanced, and there was evidence of several kinds of differentiation. A pronounced increase in the numbers of spermatozoa indicated that spermiogenesis had occurred in culture (Fig. 1B). Labelling was confined largely to spermatogonia and primary spermatocytes, with the latter labelled in all divisional

stages. Some labelled spermatids were present in all of the *Uma* cultures after 5 days at 37° C (Fig. 2), but these spermatids appeared to be newly formed and there was no labelling in spermatozoa. Thymidine incorporation, that is DNA synthesis, is completed before the onset of meiosis<sup>9,10</sup>, and so labelled spermatids must have differentiated from primary spermatocytes during cultivation. The spermiogenesis observed apparently involved differentiation of spermatids present before cultivation.

Spermatogenic arrest and progressive necrosis of all tissues occurred within 3–5 days at higher temperatures, starting at 35° C in *Anolis* and at 40° C in *Uma*. Extensive thymidine incorporation occurred even after 3 days, but there was no evidence of differentiation at these temperatures (Fig. 1C). Labelling was sparse or absent and all tissues were necrotic within the first 2–3 days in *Anolis* cultures at 40° C and in *Uma* cultures at 44° C. A marked reduction in spermatids at high temperatures suggests that these were the least heat-resistant cells in the germinal epithelium; spermatogonia appeared to be the most heat-resistant. These degenerative changes are similar to those described for the lizard testis *in vivo*<sup>6</sup>.

Fig. 2. Autoradiograph of Feulgen stained section (4µ) of a testicular explant from *Uma scoparia* labelled with 10 µc. of thymidine-<sup>3</sup>H for 10 h and cultured at 37° C for 5 days. Several spermatids labelled with thymidine are indicated by the arrows. The larger, more densely stained and labelled, primary spermatocytes are evident near the periphery of the seminiferous tubule, toward the top.

Table 1. INTERSPECIFIC EFFECTS OF TEMPERATURE ON THE CULTURED TESTIS

Temperature of Incubation ° C	<i>Anolis</i>	<i>Uma</i>
28	++	++
32	+++	++
35	+	—
37	0–+	+++
40	0	+
44		0

Three to five individuals were examined at each temperature. 0, Extensive degeneration within 3 days; +, labelling but with extensive necrosis within 5 days; ++, good maintenance but little activity; +++, maximal labelling and differentiation.

Although parallel responses to increasing temperature were observed in the testes of both species, the germinal epithelia of the more thermophilic *Uma* were clearly more heat-resistant (Table 1). The extent of this interspecific divergence in heat-resistance is about 5° C and thus corresponds closely to the difference between the average preferred body temperatures of the two lizards. This parallelism in the thermal responses of tissue and organism provides additional evidence of the physiological adjustments that underlie the selection of different body temperatures by the lizards. Furthermore, the divergence in testicular heat-resistance is very similar in magnitude to that observed in several somatic tissues from species with preferred temperatures similar to the two investigated here<sup>11</sup>.

The absolute heat-resistance of reproductive tissues and of somatic tissues in any one species may differ. If such a discordance exists, our data support the view<sup>6</sup> that it is less pronounced than in many other animals, especially the scrotal mammals. The performance of a tissue *in vitro* may not accurately reflect its performance *in vivo*, but the thermal responses of lizard testes in culture are consistent with observations on intact animals<sup>6</sup>. The testes of each species could be successfully cultured at temperatures corresponding to the range preferred by the species, but deterioration of the germinal epithelia occurred within a few days at temperatures only slightly above this level. In contrast, mammalian testes have not been successfully cultured at temperatures corresponding to their normal body temperatures, requiring instead the lower temperatures characteristic of the scrotum<sup>12</sup>.

Cowles<sup>6</sup> has postulated that the mammalian scrotum evolved during the development of homeothermy because "... the optimum body temperature eventually increased beyond the point at which reproduction was still pos-

sible. . . ." Lizards appear to have evolved the same high optimal body temperatures—their preferred levels—as have the mammals. Commensurate increases in the heat-resistance of the saurian germinal epithelium have, however, permitted the retention of the testis intra-abdominally. The longer exposure to high body temperatures in homeotherms could have been a factor in prohibiting the maintenance of the testis within the body cavity. In this regard, it would be interesting to have comparative data for the heat-resistance of germinal epithelia from homeotherms without scrota.

The saurian testes apparently represent excellent material for *in vitro* investigations of reproductive physiology. They lend themselves well to culture, and both the extent and rate of differentiation are far greater than that observed in cultured testes of other animals<sup>13</sup>.

## On Concomitant Immunity in Tumour-bearing Hamsters

by

R. K. GERSHON

R. L. CARTER\*

KAZUNARI KONDO

Department of Pathology, Yale University  
School of Medicine, New Haven, Connecticut

Hamsters grafted with a lymphoblastic lymphoma are refractory to reinoculation with cells of the same tumour, although the initial graft grows progressively. The nature, strength, and development of this "concomitant immunity" have been investigated and its possible role in the control of metastases has been discussed.

EARLY in the study of tumour transplantation, Ehrlich<sup>1,2</sup> described the phenomenon whereby animals already bearing one tumour were sometimes resistant to a second graft; the new tumour was not accepted, even though the first lesion continued to grow progressively. Similar findings were reported by other investigators and the term "concomitant immunity" was introduced by Bashford *et al.* in 1908 (ref. 3). Many features of this process were, however, obscure: its incidence and specificity were disputed and the underlying mechanisms were completely unknown. Nutritional factors were implicated by Ehrlich in his theory of athrepsis, but this was quickly discarded. More specific immunological processes were later postulated although there was little direct evidence for such views. All attempts to transmit the immune state with serum were unsuccessful and, in 1929, Woglom<sup>4</sup> observed that "the athreptic theory . . . had been overthrown, but no explanation of the resistance had been substituted". In recent years, immunological factors

controlling the growth of tumours have been widely studied but almost all this work has been concerned with immunity induced by various procedures which *prevent* the immunizing graft from progressive growth<sup>5</sup>. By contrast, concomitant immunity—in which the immunizing tumour continues to grow—has attracted little attention and many of its paradoxical features are still obscure.

Two homotransplantable lymphomata from hamsters have been investigated in this laboratory, one of which regularly induces a classical state of concomitant immunity<sup>6</sup>. In the present paper, this experimental model has been used to investigate three aspects of the subject: the transfer of concomitant immunity, its development, and its strength. Functional implications are also briefly considered and the possible role of concomitant immunity in suppressing metastatic growth is emphasized.

In the first series of experiments, young Syrian golden hamsters from an inbred line (*MHA*)<sup>7</sup> were used, weighing 75–90 g. Initially, cell suspensions of the lymphoma were prepared according to a method previously described<sup>8</sup> and  $1 \times 10^7$  cells were injected subcutaneously into the right flank of twelve donor animals. Three weeks later, when the

\* Present address: Department of Experimental Pathology, Chester Beatty Research Institute, Institute of Cancer Research: Royal Cancer Hospital, Fulham Road, London, S.W.3.

tumours were well developed and measured 2-4 cm in diameter, the hamsters were separated into two groups. Six animals were re-challenged with  $1 \times 10^8$  tumour cells grafted into the opposite flank and the remainder were killed. The tumours and spleens were removed and cell suspensions were prepared from each, mixed together in varying proportions, and inoculated into thirty-two normal isogenic recipients. Animals in the first group demonstrated the usual features of concomitant immunity; all the new tumour grafts were promptly rejected while the older lesions continued to grow. The findings in the second group are recorded in Table 1, which shows that spleen cells from tumour-bearing animals can suppress the growth of tumours in normal hamsters.

Table 1. EFFECT OF MIXING TUMOUR CELLS AND SPLEEN CELLS FROM TUMOUR-BEARING ANIMALS AND INOCULATING THE MIXTURE INTO ISOGENIC RECIPIENTS

No. of tumour cells/ml.	No. of spleen cells/ml.	No. of animals developing tumours
$2 \times 10^6$	$2 \times 10^6$	0/8
$2 \times 10^6$	$2 \times 10^7$	1/8
$2 \times 10^6$	$2 \times 10^8$	1/8
$2 \times 10^6$	$2 \times 10^9$	4/8
$2 \times 10^6$	—	8/8

Notes: (1) Tumour cells and spleen cells were mixed together and inoculated into the subcutaneous space at once, without a period of incubation; the final volume of cell suspension was 1 ml. (2) The presence of tumour in the recipient animals was assessed at autopsy, 3 weeks after grafting. These comments also apply to data presented in Tables 2 and 4.

Further experiments were carried out to test the specificity of this effect. These can be summarized as follows. (a) Cell suspensions of other organs from the original tumour-bearing hamsters—liver and kidney—failed to suppress the growth of tumours in normal recipients. (b) Spleen cells from normal *MHA* hamsters were ineffective; similarly, spleen cells from normal animals injected intravenously 2 days previously with 0.3 ml. of a solution containing 10 mg of 'Zymosan' (a non-specific stimulant of the reticuloendothelial system<sup>9</sup>) exerted no demonstrable effect. (c) Additional investigations were made, using a different homotransplantable lymphoma. The new tumour was readily accepted by animals which had recently rejected a second graft of the original tumour. Second, spleen cells from the original tumour-bearing hamsters did not inhibit the growth of the new lymphoma in normal recipients. Third, the reverse situation was also examined in which spleen cells from animals grafted with the new tumour were mixed with the original tumour and inoculated into normal hamsters; no suppression of the growth of the tumour followed. The main control experiments are shown in Table 2.

Table 2. EXPERIMENTS TO DEMONSTRATE THE SPECIFICITY OF THE SUPPRESSION OF TUMOUR GROWTH BY SPLEEN CELLS FROM TUMOUR-BEARING ANIMALS

Source and No. of tumour cells/ml.	Source and No. of spleen cells/ml.	No. of animals developing tumours
O $2 \times 10^6$	Normal $2 \times 10^7$	7/7
O $2 \times 10^6$	Normal $2 \times 10^8$	7/8
O $2 \times 10^6$	Treated with 'Zymosan' $2 \times 10^7$	5/5
O $2 \times 10^6$	Treated with 'Zymosan' $2 \times 10^8$	5/5
O $2 \times 10^6$	Animals bearing tumour D, $2 \times 10^7$	5/5
D $2 \times 10^6$	Animals bearing tumour O, $2 \times 10^7$	5/5
O $2 \times 10^6$	Animals bearing tumour O, $2 \times 10^7$	0/7

Note: In most of the tests the original tumour was used, but in two experiments a different homotransplantable lymphoma was used: the two tumours are listed as 'O' and 'D' respectively.

Repeated attempts to transfer concomitant immunity with serum from tumour-bearing animals were unsuccessful, despite the use of several different immunizing schedules; some animals received up to 5 ml. of serum, in divided doses. Similarly, all tests for cytotoxic antibodies in these sera were negative when the technique of Gorer and O'Gorman<sup>10</sup> was used. Three conclusions may be drawn. First, spleen cells from tumour-bearing hamsters can suppress tumour growth in normal isogenic recipients; second, such activity appears to be highly specific; third, serum from tumour-bearing animals is ineffective. These observations would seem to fulfil the usual criteria of an immune reaction mediated by cells.

Table 3. DEVELOPMENT AND STRENGTH OF CONCOMITANT IMMUNITY IN TUMOUR-BEARING HAMSTERS

Immunizing graft tumour cells/ml.	Second challenging graft tumour cells/ml.	Time of challenge days	No. of developing tumours
Test animals			
$1 \times 10^7$	$1 \times 10^6$	7	2/8
$1 \times 10^7$	$1 \times 10^6$	14	0/8
$1 \times 10^7$	$1 \times 10^6$	21	0/6
$1 \times 10^7$	$1 \times 10^7$	7	6/8
$1 \times 10^7$	$1 \times 10^7$	14	0/8
$1 \times 10^7$	$1 \times 10^7$	21	1/6
$1 \times 10^7$	$1 \times 10^8$	7	8/8
$1 \times 10^7$	$1 \times 10^8$	14	1/8
$1 \times 10^7$	$1 \times 10^8$	21	5/6

Control animals (hamsters from the same series which did not receive an immunizing tumour graft at day 1)

—	$1 \times 10^6$	7	4/5
—		14	5/5
—		21	5/5
—	$1 \times 10^8$	7	2/5
—		14	3/5
—		21	2/5

A second series of investigations was carried out to determine the strength of this immune state. Sixty-six normal hamsters received a subcutaneous graft of  $1 \times 10^7$  tumour cells and were subsequently re-challenged in the opposite flank with a second tumour graft. Different concentrations of cells and different times of challenge were tested and the results are summarized in Table 3. Predictably, the size of the challenging graft and the stage at which it was inoculated were found to be important factors, but it is clear that the state of concomitant immunity is quickly established and is remarkably potent. At its height, animals can reject 100,000 more cells than are necessary to produce tumours in normal control hamsters. Despite this, we would again emphasize that, in each case, the immunizing tumour continues to increase in size.

Additional experiments were performed to establish an approximate comparison between the strength of concomitant immunity and that obtained by other workers in specifically immunized animals. Old and his colleagues<sup>11-13</sup> investigated the transfer of immunity with peritoneal cells from such animals and their techniques were closely followed. Five donor *MHA* hamsters received a subcutaneous graft of  $1 \times 10^7$  cells. When the tumours were 2-4 cm in diameter, a peritoneal exudate was raised with a single injection of a 3 per cent starch solution, using the method of Bennett<sup>13</sup>. Two days later, the peritoneal cells were recovered by washing out the abdominal cavity with sterile culture medium ('M 199'); cell suspensions were prepared, mixed with tumour cells and inoculated into sixteen normal isogenic recipients. The results are summarized in Table 4 and indicate that peritoneal cells, combined with tumour cells in a ratio of 1:10, can suppress tumour growth in normal animals; peritoneal cells from normal animals are ineffective. The difficulties in comparing such findings with those previously reported, obtained from different experimental models, will be obvious; but it seems reasonable to conclude that the strength of the immune state is at least broadly comparable in the two circumstances.

The present findings show that concomitant immunity in tumour-bearing hamsters is a strong, highly specific process, mediated by immune cells which can suppress tumour growth in normal isogenic recipients. The co-existence of a progressively growing tumour and a large number of immune cells is particularly interesting in view of recent work by Mikulska *et al.*<sup>14</sup>, who demonstrated that autochthonous spleen cells from

Table 4. EFFECTS OF MIXING TUMOUR CELLS AND PERITONEAL CELLS FROM TUMOUR-BEARING ANIMALS AND INOCULATING THE MIXTURE INTO ISOGENIC RECIPIENTS

No. of tumour cells/ml.	No. of peritoneal cells/ml.	No. of animals developing tumours
$1 \times 10^6$	$1 \times 10^6$	0/8
$1 \times 10^6$	$1 \times 10^8$	0/8
$1 \times 10^6$	$1 \times 10^8$ normal cells	8/8

rats with fibrosarcomata induced chemically did not suppress tumour growth in isogenic recipients unless the primary tumour was resected 3 weeks before the spleen cells were obtained. It should, however, be emphasized that the experimental system used in this work differed in many respects from our own.

It is also clear that, judging by the quantitative results of the studies of cell transfer, concomitant immunity is extremely potent. Comparison with results from other experimental models is hazardous, but it appears that, at its height, the immune state is at least roughly comparable with that produced in animals immunized with tumours which do not grow progressively. In the face of this strong concomitant immunity, other mechanisms which have been postulated to explain the progressive growth of immunizing tumour grafts—self-enhancement<sup>15</sup>, inadequate antigenic stimulation<sup>16</sup>, impaired immune responses<sup>16</sup>—do not seem to be operative in the present circumstances.

It is likely that concomitant immunity has important functional implications, notably in suppressing metastatic growth. Evidence that immunological factors may participate in controlling the metastatic spread of tumours has been presented by Feldman and Yaffe<sup>17</sup>, and a direct association between concomitant immunity and the suppression of metastasis was postulated many years ago by Gay<sup>18</sup>; but, as in so many other aspects of this subject, the older data are conflicting. Four features suggest that such a relationship may exist, at least with the hamster lymphoma under investigation. (i) Although this tumour is poorly differentiated and grows very rapidly, it does not metastasize: at least 2,000 autopsies have been carried out on these animals since 1964, but deposits of secondary growth have never been found. (ii) Despite this, tumour cells soon appear in the circulation and persist until the death of the animal. They are clearly viable because subcutaneous inoculation of whole blood into normal recipients produces a high incidence of tumours<sup>6,19</sup>. (iii) Tumour cells are also demonstrable in the regional lymph nodes<sup>8,20,21</sup>. A vigorous histological reaction is mounted but, again, viable cells must be present in considerable numbers; if cell suspensions are prepared from these nodes and inoculated into normal animals, many of the recipients develop tumours, an effect which is demonstrable throughout the life span of the tumour-bearing animal<sup>19</sup>. (iv) Some preliminary observations indicate that if the tumour is grafted into animals which are treated with an immunosuppressive agent—a rabbit anti-hamster thymocyte serum, raised according to the method

of Levey and Medawar<sup>22</sup>—important changes are produced: first, the tumour quickly metastasizes to regional and mediastinal nodes; second, concomitant immunity appears to be abrogated. These observations are now being extended and, when complete, will be reported separately, but they are clearly relevant to the present argument.

Certain limitations of our experimental model will be obvious. The tumour used to induce concomitant immunity has been maintained by serial transplantation for several years: its antigenic structure is, as yet, unknown and it is not isologous with respect to the test animals. The findings reported here emphasize, rather than resolve, the paradox of concomitant immunity and no mention has been made of possible mechanisms whereby the immunizing tumour is able to resist destruction and grow progressively; this aspect has, however, been under investigation and will be the subject of a separate paper. The most important aspect of the present work is the demonstration that progressive growth of a tumour is not incompatible with a strong, specific immune response.

## Inhibition of Tumour Cell Viability by DNA

by

J. LESLIE GLICK

ANTHONY P. SALIM

Roswell Park Memorial Institute (New York State Department of Health), Buffalo, New York

Specific preparations of DNA inhibit the viability of specific tumour cell lines. The effect may be due to some special characteristic of the DNA molecule, such as a specific region of nucleotide sequence, as well as molecular size, shape or charge.

It has been demonstrated that mouse thymus DNA specifically inhibits the growth of L1210 tumours, when L1210 cells are incubated with DNA and then injected subcutaneously into mice<sup>1-3</sup>. DNA from both L1210 and *Escherichia coli* is ineffective. Degradation by deoxyribonuclease (DNase), denaturation by heating to 100° C, or ultra-violet irradiation of the mouse thymus DNA abolish its ability to inhibit growth. Treatment with ribonuclease (RNase), or heating to 60° C, however,

permits the inhibition by DNA of tumour growth. Additional work has shown that mouse thymus DNA but not L1210 DNA, *E. coli* DNA, or DNA from mouse thymus treated with DNase, inhibits the viability of L1210 cells *in vitro*<sup>2-5</sup>. The mouse thymus DNA, but not L1210 DNA or *E. coli* DNA, also stimulates synthesis of DNA and RNA before inhibiting the viability of L1210 cells<sup>4,6</sup>. Results obtained with the use of specific metabolic inhibitors at particular intervals of time suggest that at least some of

the RNA enhanced with DNA is directly transcribed by the mouse thymus DNA rather than only by the DNA of the L1210 cells (Glick, J. L., and Sahler, C., to be published). These experiments all indicate that the action of mouse thymus DNA on L1210 cells may result from some special characteristic of the DNA, such as a specific region of nucleotide sequence, besides more general properties such as molecular size, shape, and charge. The present report supports this hypothesis, because only specific preparations of DNA were found to inhibit the viability of specific cell lines.

DNA was prepared from mouse thymus, mouse liver, mouse spleen, calf thymus, human spleen, human leukaemia, L1210 mouse leukaemia, and SB1 hamster small bowel carcinoma. Except for the DNA from calf thymus, all the other preparations of DNA were isolated by the method of Szybalska and Szybalski<sup>6</sup> in this laboratory. The calf thymus DNA was obtained commercially but was purified<sup>6</sup> by us. Human spleen DNA was obtained separately from two female patients (aged 46 and 48 years, respectively), whose spleens were diagnosed free of disease. Human leukaemia DNA was obtained from cell line RPMI No. 5630 (originating from a chronic myelogenous leukaemia) cultured in medium RPMI No. 1640 plus 10 per cent foetal calf serum. The mouse DNA preparations were all obtained from young male DBA2 mice. L1210 DNA and SB1 DNA were obtained from L1210 cells cultured in medium RPMI No. 1634 plus 5 per cent foetal calf serum, and from SB1 cells cultured in medium RPMI No. 1640 plus 5 per cent foetal calf serum, respectively. All DNA preparations were treated with RNase and repurified<sup>6</sup> before use. In some cases mouse thymus DNA and human spleen DNA were degraded with DNase<sup>6</sup> in order to make them biologically inactive.

The following cell lines were treated with DNA: L1210 mouse leukaemia (RPMI No. 3116), S-37 mouse sarcoma, S-180 mouse sarcoma, Ehrlich mouse carcinoma, human leukaemia RPMI No. 1245 (originating from a chronic myelogenous leukaemia), human lymphoma P-3J (a Burkitt lymphoma), and human mesothelioma (RPMI No. 212). L1210 cells were grown *in vitro*, as already noted. S-180 and Ehrlich cells were maintained in the ascitic form in male Swiss mice. S-37, human leukaemia RPMI No. 1245, human lymphoma, and human mesothelioma cells were cultured in media RPMI No. 1640 plus 20 per cent foetal calf serum, RPMI No. 1634 plus 10 or 20 per cent foetal calf serum, RPMI No. 1640 plus 10 per cent foetal calf serum, and McCoy medium plus 10 per cent foetal calf serum, respectively. In all experiments cells were washed several times at 2°C and then very slowly shaken at 37°C in 4 ml. of a phosphate-buffered saline<sup>6</sup>, pH 7.5, containing 5.5 mmolar glucose and 0.2 mmolar spermine tetrahydrochloride. The cells (10<sup>6</sup>/ml.) were treated for 30 min with DNA (60 µg/ml.), then washed at 2°C and re-incubated at 37°C in 4 ml. of phosphate-buffered saline containing glucose and free of DNA but not spermine. Control cells were incubated for 30 min without DNA and then washed and re-incubated in a similar fashion to the cells treated with DNA.

Cell viability was determined by adding 0.2 ml. of 0.1 per cent trypan blue (dissolved in Hanks balanced salt solution) to 0.2 ml. of cell suspension; only unstained cells were considered viable<sup>7,8</sup>. Furthermore, cell lysis proceeded most readily when the percentage of stained cells was high, thus indicating that uptake of dye reflected the death of cells rather than mere changes in permeability<sup>4</sup>. In the experiments described here the number of viable cells in each group treated with DNA was compared with the number of viable cells in the corresponding control group. This viability index of the cells treated with DNA was then expressed as a percentage change from the control cells.

The results listed in Table 1 summarize the effects of various DNA preparations on the viability of L1210 cells. Those DNA preparations which depressed cell viability

were about equally effective. In Fig. 1a, therefore, the results of the inhibitory DNA solutions (group I) were pooled, as were the results of the non-inhibitory DNA solutions (group II). At least three points are worth considering. (i) Inhibition of cell viability was not apparent during the initial 30-min exposure of L1210 cells to "group I DNA". Such inhibition, however, did develop on re-incubation of the cells in the absence of DNA. (ii) Cell death was induced with mouse DNA isolated from two other normal tissues besides thymus. In contrast, L1210 DNA, which was obtained from malignant mouse cells grown either *in vivo*<sup>2,3</sup> or *in vitro*, had no effect on cell viability. (iii) Inhibition by DNA of the viability of L1210 cells was dependent on the species from which the DNA was derived. Thus, DNA prepared from calf or human normal tissues or from hamster malignant tissue was not inhibitory.

Table 1. RESPONSE OF L1210 CELLS TO VARIOUS DNA PREPARATIONS

DNA preparation	Inhibition of cell viability
Group I	
Mouse thymus DNA	+
Mouse liver DNA	+
Mouse spleen DNA	+
Group II	
Calf thymus DNA	0
Human spleen DNA	0
Mouse leukaemia L1210 DNA	0
Hamster carcinoma SB1 DNA	0
DNase-treated mouse thymus DNA	0

+, Inhibition (cell viability at least 20 per cent less than that of the control cells, at 90 and 120 min after removal of the DNA); 0, no effect (cell viability within  $\pm 5$  per cent of that of the control cells, at 90 and 120 min after removal of the DNA).

Table 2. RESPONSE OF VARIOUS CELL LINES TO MOUSE THYMUS DNA

Cell line	Viability inhibited
Group A	
Mouse leukaemia L1210	+
Mouse sarcoma S-37	+
Mouse sarcoma S-180	+
Group B	
Mouse carcinoma (Ehrlich)	0
Human leukaemia RPMI No. 1245	0
Human mesothelioma RPMI No. 212	0

+, Inhibition; 0, no effect. See Table 1 for definitions of inhibition and no effect.

Table 2 lists several cell lines which were susceptible to mouse thymus DNA, as well as those cell lines which were not affected. Although three different mouse tumour lines were inhibited to the same degree by mouse thymus DNA, a fourth line—Ehrlich ascites cells—was not affected. Two different human tumour lines also were not inhibited by mouse thymus DNA. Fig. 1b combines the results of mouse thymus DNA on the susceptible cell lines (group A) and on the resistant lines (group B). The extent of inhibition caused by mouse thymus DNA on any of the three susceptible cell lines was similar to that caused by any of the group I preparations of DNA on L1210 cells (Fig. 1).

Figs. 2 and 3 demonstrate the inhibitory properties of the different human DNA preparations. Normal human spleen DNA inhibited the viability of two different human tumour cell lines—leukaemia RPMI No. 1245 (Fig. 2) and lymphoma P-3J (results not shown)—although it had no effect on L1210 cells (Table 1). Degradation of human DNA by DNase removed its inhibitory property (Fig. 2). Intact DNA prepared from human leukaemia RPMI No. 5630 did not inhibit cell viability of leukaemia RPMI No. 1245 but did depress cell viability of lymphoma P-3J (Fig. 3).

Smith and Cress<sup>9,10</sup> observed DNA inhibition of cell viability, but their results did not indicate the type of specificity reported here. They found that DNA preparations from both tumours and normal tissues were toxic to L cells in tissue culture. High concentrations of DNA (250–5,000 µg/ml.) were required, however, to cause the cells to die, and the DNA was added permanently to the culture medium. Toxic effects were not observed until

Fig. 1. *a*, Effects of various DNA preparations on L1210 cells; *b*, effects of mouse thymus DNA on various cell lines. The results obtained with the various DNA preparations listed under groups I and II in Table 1 were pooled respectively in *a*. The results obtained with the various cell lines classified under groups A and B in Table 2 were pooled respectively in *b*. Each of the three types of DNA belonging to group I was used in three or four experiments, a total of ten experiments being performed. Likewise, duplicate experiments were performed with each of the five types of DNA belonging to group II. Triplicate experiments with mouse thymus DNA were performed on each of the three cell lines belonging to group A, and duplicate experiments with mouse thymus DNA were performed on each of the three cell lines belonging to group B. The solid line designated by group I and the broken line designated by group II each represent the mean of ten experiments,  $\pm$  S.E.M. The solid line designated by group A represents the mean of nine experiments,  $\pm$  S.E.M., and the broken line designated by group B represents the mean of six experiments,  $\pm$  S.E.M. Control experiments, in which cells were incubated without DNA, were performed with each DNA experiment.

12 h after DNA had been added. Thus, the disparity between our results and those of Smith and Cress may perhaps be attributed to the different conditions of incubation. Our results demonstrate that under appropriate conditions the origins of both the exogenous DNA and the host cell line determine whether or not the DNA inhibits the viability of the cells. This finding is consistent with the suggestion that the base sequence of the DNA is somehow involved in causing the cells to die. There are several possibilities which may determine whether a given cell line will remain unaffected after exposure to a specific exogenous DNA. (i) Various cell lines may be able to

degrade the entering nucleic acid almost immediately<sup>11,12</sup>. (ii) Some cell lines may either repress transcription of information initiated by exogenous DNA or inactivate end-products or proteins resulting from the translation of this information. (iii) Other cell lines may lessen the availability of their enzymes for synthetic processes involving a foreign DNA. (iv) Exogenous DNA may bring about the death of cells by inducing the formation of gene products which may interact only with specific antigenic constituents of particular cell lines (Glick, J. L., and Sahler, C., to be published). The absence of these antigenic constituents in other cell lines would preclude the recognition and destruction of the host cells by the newly formed gene products. (v) The viability of the cells can be enhanced by DNA when incubation conditions are altered<sup>13</sup>; this phenomenon is independent of the type of DNA used and does not appear to be caused by extensive degradation of the DNA. Thus, in some cell lines specific inhibition of cell viability might be counterbalanced by non-specific enhancement, so that cell viability would not be affected by the DNA.

Fig. 3. Effects of intact DNA which had been obtained from human leukaemia RPMI No. 5630 on human leukaemia RPMI No. 1245 and human lymphoma P-3J. The solid line designated by lymphoma P-3J represents the mean of four experiments,  $\pm$  S.E.M. The broken line designated by leukaemia 1245 represents the mean of seven experiments,  $\pm$  S.E.M. Control experiments, in which cells were incubated without DNA, were performed with each DNA experiment.

We thank Dr. George E. Moore for providing us with the various human cell lines. This work was supported in part by a grant from the U.S. Public Health Service.

## Two ATPases in the Sarcoplasmic Reticulum of Skeletal Muscle Fibres

by

F. GIACOMELLI  
C. BIBBIANI  
E. BERGAMINI  
C. PELLEGRINO

Istituto di Patologia Generale, University of Pisa,  
Italy, and Istituto di Patologia Generale, University  
of Messina, Italy

Two distinct ATPase activities have been localized on the sarcoplasmic reticulum of muscle cells. They may play a part in contraction and relaxation.

THERE are two systems of membranes between the myofibrils in the sarcoplasmic spaces of skeletal muscle fibres: the sarcoplasmic reticulum (SR) and the transverse tubular system (T)<sup>1</sup>. They are in intimate contact in correspondence of the triads<sup>2</sup> but they do not communicate directly with each other.

Recent investigations<sup>3-7</sup> make it clear that the T system is an invagination of the sarcolemmal membrane, thus fulfilling the main requirement for a pathway to spread activation to the fibrils. On the other hand, the sarcoplasmic reticulum is a prominent part of the contraction-relaxation mechanism<sup>8-11</sup>. The probable physiological activator of contraction, that is, calcium ions<sup>12</sup>, is captured within the lateral sacs of the triad when the muscle is in the resting state and is released from them during contraction<sup>13,14</sup>. ATP localized in restricted areas of the reticulum<sup>15</sup>, which might correspond to the triadic sites, could furnish the high energy phosphates needed for this phenomenon to take place<sup>9,16</sup>.

Histochemistry under the optical microscope indicates the existence of an ATPase at the level of sarcoplasmic reticulum<sup>17</sup> and triads<sup>18</sup> of skeletal muscles. Moreover, biochemical investigations have shown that the sarcotubular fraction has a magnesium-stimulated ATPase which is inhibited by calcium in the presence of magnesium<sup>19-21</sup>. Moreover, a sodium-activated ATPase has been found in the microsomal fraction of frog<sup>22</sup> and rabbit striated muscle<sup>23</sup>. Biochemical techniques do not, however, allow a precise localization of these enzyme activities in relation to the differentiations of structure in the sarcoplasmic reticulum. Histochemical techniques applied to electron microscopy may well overcome these limitations. In fact, recent electron microscope observations showed that a magnesium-activated ATPase occurs in the lateral sacs of the diads and triads of dog<sup>24</sup> and rat<sup>25,26</sup> myocardium, in the sarcoplasmic reticulum and T system of frog skeletal muscle<sup>27</sup> and in the correspondence of the triad components of *Opsanus tau* gas bladder muscle<sup>28</sup>. In the present article the characterization and localization of ATPase in the sarcoplasmic reticulum of frog and rat muscles have been investigated using this technique.

Frog ileofibularis and rat extensor digitorum longus muscles were tied at their resting lengths on strips of wood and fixed in cold 6.25 per cent glutaraldehyde buffered with 0.2 molar sodium cacodylate, pH 7.2, for 30-45 min. The fixed muscles were cut transversely in 3-4 mm pieces, washed in cold 0.1 molar sodium cacodylate, pH 7.2, and stored for 36 h in the same buffer at 0°-4° C. Thick (50-60 $\mu$ ) sections were cut on a freezing microtome and immersed in buffer for 15-20 min. Freely floating sections, briefly washed in distilled water, were incubated for 5-60 min at 37° C in a Wachstein and Meisel<sup>29</sup> medium

Fig. 1. Frozen section from frog muscle incubated for 60 min with magnesium and ATP as substrate. Reaction product is concentrated within the lateral sacs of the triad (arrows). Longitudinal portion of the SR (L) shows very low amounts of reaction product; none is present in the central tubule of the triad (T). ( $\times 45,600$ .)

Fig. 2. Frozen sections from frog muscle incubated for 15 min in the presence of (a) magnesium alone, (b) calcium alone, (c) magnesium and calcium, with ATP as substrate. The reaction product is restricted to the lateral sacs of the triad. Smaller deposits of final product can be seen when magnesium is replaced by calcium (b); no significant decrease of reaction product when both magnesium and calcium are present (c). ( $\times 52,800$ .)

containing substrates, lead nitrate as the capture reagent and equimolar concentrations of ATP and magnesium<sup>30,31</sup>.

Similar media at the same pH, containing AMP, ADP, IDP, ITP, TPP or  $\beta$ -glycerophosphate as substrates, were also tested. In each case control preparations were incubated in media from which the substrates were omitted.

After incubation the sections were rinsed briefly in distilled water, post-fixed in cold 2 per cent osmium tetroxide buffered with veronal-acetate to pH 7.4, with added sucrose, for 30 min, dehydrated in graded ethanol and embedded in 'Epon 812'<sup>32</sup>. Thin sections were cut on a Porter-Blum microtome, and examined under an electron microscope.

When the effects of activators or inhibitors of the enzyme activity were studied, thick sections prepared from the same piece of muscle were incubated and treated in parallel. The results were assessed by examining thin sections prepared from at least three blocks derived from different thick frozen sections. Only the results obtained in the well fixed peripheral region of the muscle were retained.

In longitudinal sections, incubated with magnesium and using ATP as substrate, the final product of the enzyme activity is mainly concentrated within the lateral sacs of the triad, while the longitudinal portion of the sarcoplasmic reticulum shows much smaller amounts of lead phosphate (Fig. 1).

With ADP, IDP, ITP or TPP as substrates the location of the precipitate is similar to that with ATP. The sections incubated with AMP show no reaction product within the reticulum.

Incubations which were run simultaneously in the presence of magnesium alone, calcium alone or magnesium and calcium (all 2 mmolar), under ATP as substrate, show smaller deposits of the final product when magnesium is replaced by calcium and no significant decrease of the final product when both magnesium and calcium are present (Fig. 2). Possibly, the failure to find inhibition by calcium is due to the retention of sufficient amounts of calcium in the SR of the fibre in the basal condition of incubation.

If magnesium and ATP are used in equimolar concentrations the simultaneous presence of sodium (125 mmolar) and potassium (12.5 mmolar) leads to a marked additional deposition of lead phosphate within the lateral sacs of the triad (Figs. 3 and 4).

Ouabain (1 mmolar), a specific inhibitor of transport ATPase, completely inhibits this additional activation of the magnesium dependent ATPase activity (Figs. 3 and 4). These effects are more evident when shorter incubation times (5–15 min) are used. At the level of the sarcolemma, particularly on the membrane of the pinocytotic vesicles, activation of ATPase by monovalent cations and inhibition by ouabain were also evident.

In sections incubated with  $\beta$ -glycerophosphate as substrate no reaction product is encountered in the terminal segments of the sarcoplasmic reticulum, whereas lead phosphate is deposited at the level of the sarcolemmal membrane.

Fig. 3. Frog muscle incubated in parallel for 15 min with magnesium-ATP equivalent medium. (a) Fine granular lead phosphate deposit in the lateral sacs of the triad in the presence of magnesium alone. (b) Heavy lead phosphate precipitate can be seen when sodium and potassium are simultaneously added. (c) Ouabain (1 mmolar) clearly decreases the additional amount of precipitate of the final product seen in b. ( $\times 53,200$ .)

In order to test the specificity of the localization of the enzyme activity, floating sections were immersed in 1 per cent buffered lead nitrate, pH 7.2, for 15 min and then incubated for the same length of time in a solution of inorganic phosphate in order to produce lead phosphate (Page and Gillis, personal communication).

This control showed, both in the frog and in the rat muscles, that lead phosphate deposits were absent from the reticulum but present in coarse aggregates on the myofibrils, mainly in conjunction with the corresponding peripheral part of the A band (Fig. 5).

Our observations show that both ATPase activities, one stimulated by magnesium and the other activated by sodium and potassium, are located chiefly at the level of the outer sacs of the triad, and are far less evident, although they are not absent, at the correspondence of the longitudinal portion of the sarcoplasmic reticulum.

This topographical difference may reflect the real situation, or may be due to the effect of different susceptibilities of the enzymes present in the two parts of the SR to the inactivating action of the fixative. In both cases, however, the inactivating action of the fixative shows a clear heterogeneity.

In the intermediate component of the triad, the T tubule, no ATPase or other phosphatase activity was ever detected. This contrasts with the findings of Zebe<sup>27</sup> obtained after very short fixation with osmium tetroxide, with the possibility of artefacts due to the diffusion of soluble enzymes from unfixed tissue.

Fig. 4. Rat muscle incubated in parallel for 5 min with magnesium-ATP equivalent medium. (b) Reaction product is present when sodium and potassium are added. No reaction product can be seen if magnesium is used alone (a) or ouabain is added (c) to the medium used in (b). ( $\times 59,200$ )

Fig. 5. Frog muscle immersed in 1 per cent lead nitrate for 15 min and then incubated in an inorganic phosphate solution for 15 min. Coarse aggregates of reaction product can be seen at the peripheral part of the A band. ( $\times 9,200$ )

Deposition of lead precipitate has regularly been observed within the terminal sacs of the triad. This finding is similar to that of Essner *et al.*<sup>25</sup> in the sarcoplasmic reticulum of rat heart. The question then arises whether this localization is apparent, that is, is due to enzyme activity at the level of the membrane which limits the cisternae, with subsequent diffusion and fixation of the reaction product in the interior of the cisternae, or whether it is real, implying that both ATPase activities are present inside the terminal sacs of the SR. Although it does not at present seem possible to settle this question, it must be emphasized that such localization has also been observed after very short periods of incubation (down to 5 min), a situation which should minimize possible diffusion artefacts. The contents of the cisternae may have a strong affinity for the lead precipitate, but the negative results of the controls with phosphate and lead do not support this possibility. Finally, it is known that, particularly after fixation with glutaraldehyde, the outer sacs of the triad show a clear opaque content<sup>6,23-25</sup>, which may be the structural framework for the enzymes the activity of which has been detected here. The discrepancies between our demonstration of the presence of an ATPase activated by sodium and potassium and inhibited by ouabain in the lateral sacs of the triad, and the failure of Fratantoni and Askari<sup>23</sup> to find such activity in a sarcotubular cell fraction, may be due to the composition of the microsomal fraction tested, which had a very low calcium uptake, and from which the lateral sacs of the triad might have been almost absent.

So far as the physiological significance of these findings is concerned, the striking fact emerges that the sites which, according to Hasselbach<sup>13</sup> and Costantin, Franzini-Armstrong and Podolsky<sup>14</sup>, function as calcium sinks during relaxation of the muscle fibre are also the seats of at least two distinct ATPase activities. On the basis of biochemical experiments on sarcotubular fractions there seems to be a relationship between ATPase and calcium sequestration<sup>8-10,19,21,26</sup>. The present results, which show

an exact structural coincidence between these two processes, give further weight to such an association. Besides, the experiments of Hill in toad muscle<sup>15</sup> showed that ATP is located between the fibrils in the I band, almost certainly in a component of the reticulum, although there is insufficient evidence for its identification with the triadic elements. This finding at least indicates a very close proximity between the two ATPases and their specific substrate.

As regards the ATPase stimulated by sodium and potassium, it should be noted that its presence in the SR parallels the finding that this enzyme is present in the microsomal fraction isolated from various other types of cells. In these, however, fragments of plasma membrane, which is known to possess ATPase activity, are likely to be present, and this could prevent a strict intracellular localization of the enzyme, whereas in our experiments it has been possible to localize it.

We thank Miss Mara Rossini, Mrs. Lucia Giaccardo, Mr. Armando Pozzolini and Mr. Ennio Taccini for skilled technical assistance.

## Toxicity of Serum from Irradiated Donors

by

JOHN GARCIA

Massachusetts General Hospital

The "radiation sickness" which many mammals suffer may be due to a circulating by-product of energy absorption with toxin-like effects. When rats drink water flavoured with saccharin and are injected with serum from irradiated donors, they develop an aversion to this fluid. This effect had previously been observed in directly irradiated and poisoned animals.

MANY mammalian species, including man, display the syndrome of "radiation sickness" within a few hours after an exposure to sublethal doses of ionizing radiation. This may include nausea, emesis, and gastro-intestinal malaise. One of the most sensitive measures of this effect in experimental animals is the conditioned aversion test<sup>1</sup>. In essence, this test consists of giving an animal a distinctive solution (for example, water flavoured with saccharin) to drink in conjunction with radiation exposure. A single association of drinking the distinctive solution followed by radiation sickness will cause animals to learn to avoid the test fluid. Thus, a whole-body exposure to 10-30 r. will produce a significant reduction in the preference of a rat for saccharin<sup>2</sup>.

Various investigations suggest that this effect results from a circulating substance produced by the absorption of energy in the tissues of the exposed animal. First, the magnitude of the conditioned aversion response is related to total dose and is relatively independent of dose rate. Equivalent total doses produce similar effects though

exposure durations vary from minutes to hours. Second, the conditioned aversion can be produced by irradiation of a portion of the body, but the effect is not so great as if the whole body were exposed<sup>3</sup>. If two rats are joined by skin-vascular anastomosis, then the conditioned aversion response can be observed in a shielded animal when its partner is irradiated<sup>3</sup>.

If absorption of ionizing radiation by the organism does result in a stable circulating by-product with toxin-like effects on the behaving organism, then the serum from irradiated donor animals should produce the conditioned aversion response in non-irradiated recipient rats. The present experiment was conducted to test this inference.

White adult laboratory rats (Sprague-Dawley) were used as donors and recipients. The experimental donors received approximately 30 krads in 45 sec in a cobalt-60 irradiation unit recently described<sup>4</sup>. Two to four hours after irradiation, they were bled by cardiac puncture. The blood was allowed to stand for about 30 min-2 h before it was centrifuged at 2,800 r.p.m. for 20 min and

Fig. 1. The effect on the consumption of saccharin-water (large dots) by recipient rats, induced by associated injections of serum from irradiated (30 krad) donor rats. The small dots indicate the intake of tap-water on days between treatments. Control recipients, injected with serum from non-irradiated donors, did not learn to reject differentially the saccharin-water associated with injections.

then the serum was pipetted off and pooled. Thus, the recipients of serum received injections approximately 7 h after irradiation and 3–5 h after bleeding. The control donors were treated in an identical fashion except that they were not irradiated. Because 30 krad produced an obvious stress in the irradiated donors, the control donors were also stressed with a series of shocks (ten 0.5 sec pulses at 1.0 m.amp) during the period of confinement. These animals were lightly anaesthetized with ether for the cardiac puncture.

The recipient animals were maintained in individual cages and dry 'Purina' laboratory chow was freely available to them. Drinking was restricted to a 10 min period each day and the amount of the fluid intake was recorded. After a week of habituation to this schedule, the experimental treatment began.

Experimental treatment consisted of flavouring the drinking water by adding 1 g of saccharin/l. of water and allowing the animals to drink for 10 min as usual. Five minutes after the drinking period, the animals received an intraperitoneal injection of 4 ml. serum from irradiated donors. Two more injections were given at 15 min intervals so that each rat received 12 ml. on each treatment day. The recipient controls were treated identically except that they received serum from the non-irradiated control donors.

All recipients were offered water flavoured with saccharin every third day, and they received the treatment of multiple injections after drinking saccharin on the first four occasions. The last three occasions served as a measure of recovery of the effect of the injection series.

A second experiment was conducted with identical radiation and treatment conditions except that all the serum was collected from non-irradiated donors and frozen for storage. Several weeks later the serum was thawed to room temperature and then equal portions were exposed to 30 krad and injected into experimental recipients. Control animals received equal portions which had not been exposed.

After a single association of drinking water flavoured with saccharin followed by injections of serum from irradiated donors, the experimental recipients drank less water flavoured with saccharin than did the control recipients which were injected with serum from non-irradiated donors ( $P=0.05$ , ranks test). It should be recalled that the treatment of multiple injections follows the period of drinking saccharin so that the effect of the

first treatment is seen on the next period of drinking saccharin 3 days later (Fig. 1). The difference between experimental and control recipients increased with each treatment, so that after two injections this difference was highly significant ( $P<0.01$ ), and after four treatments there was no overlap in the distribution of saccharin intake scores of the two groups. In the absence of further treatment, experimental recipients began to increase their intake on the final two saccharin days, but the difference between the two groups remained significant ( $P<0.01$ ).

In contrast, no differential effect was observed in the second experiment, where the serum was exposed to 30 krad *in vitro*, that is after it was extracted from the donors. A statistical summary of the results of both experiments following four treatments is presented in Table 1. These results indicate that the aversive response does not arise from a direct effect of radiation on serum. Furthermore, because the control donors were stressed with electric shock and confinement, the effect is probably not due to a general stress factor such as an elevated concentration of adrenocortical steroids.

Table 1. CONSUMPTION OF SACCHARIN-WATER BY RECIPIENT RATS AFTER FOUR ASSOCIATIONS OF DRINKING SACCHARIN-WATER FOLLOWED BY INJECTIONS OF 12 ML. SERUM

Serum	N	Mean (ml.)	Range (ml.)
From irradiated donors	9	6	1–11
From non-irradiated donors	9	16	13–19
Irradiated <i>in vitro</i>	4	17	15–19
Non-irradiated <i>in vitro</i>	3	19	13–24

The aversive response displayed by the animals is equivalent to that observed when animals are directly treated with a series of 10–30 rads. Although it is not possible to be certain that the mechanism underlying the response produced by direct exposure of the animal is identical with that produced by injection of serum from irradiated donors, it is interesting to note that direct collimated exposure of the hip region of the rat is as effective as head exposure which indicates that the former effect probably does not result from irradiation of a specific class of tissue. On the other hand, exposure of a comparable area of the abdomen is about five times as effective as any other region. This may mean that the interaction of ionizing radiation with intestinal flora, waste, or food metabolic products is especially effective in the production of toxin-like substance or substances<sup>1</sup>.

In a series of investigations which in many ways parallel the saccharin aversion studies but differ in method, Steadman<sup>2,3</sup> has reported the isolation of a toxic substance from the urine of irradiated rabbits which, when injected intraperitoneally into non-irradiated test rabbits, produces many of the symptoms of acute radiation sickness. Only a small amount of this substance was found in the urine from normal controls. Furthermore, the time course of symptoms, particularly tachycardia, after injection of the toxic material from the urine of irradiated animals is similar to the time course of the development of the saccharin aversion after irradiation. Thus, it may be that this substance of yet unknown chemical composition may be the by-product of radiation exposure which produces radiation sickness and the conditioned aversion response.

This work was supported by a contract with the U.S. National Aeronautics and Space Administration and a U.S. National Institutes of Health career award to F. R. E. We thank Dr. K. Stratton for her advice on radiation exposure and dosimetry.

# Proteins in the Cell Walls of Some Green Algae

by

E. W. THOMPSON  
R. D. PRESTON

Astbury Department of Biophysics,  
University of Leeds

Analysis of algal cell wall fractions suggests the presence of protein bound to the wall much as in higher plants.

THE frequently expressed belief that protein is present in plant cell walls, otherwise exclusively carbohydrate, seems finally to have been confirmed<sup>1</sup>. This confirmation stems from the demonstration that when a cell is fractionated a protein containing hydroxyproline also described elsewhere<sup>2</sup> separates in the main with the cell wall fraction and is firmly bound to the cell wall. This is one of the few proteins known other than collagen to contain this amino-acid. Unlike collagen, however, the protein—if a single protein only is involved—also contains cystine and, while hydroxyproline could serve only as a marker, it is to cystine that Lamporte looks for the function of the protein, based obliquely on the known effects of S-S bond splitting agents on yeast cell walls<sup>3</sup>. He gives good reason for the view that the protein is involved in the extensibility of cell walls during cell growth, and he has provisionally given it the name "extensin"<sup>1</sup>. All the evidence for the occurrence of this protein comes from higher plants; but it is evident that if it is of any fundamental significance it must also occur in lower plants. We have therefore examined a number of algae in an attempt to determine (a) whether a protein containing hydroxyproline occurs also in these plants; (b) whether the protein is associated with the cell wall; and (c) whether the protein is of a kind making it a likely candidate for the proposed role in extension. This is a preliminary account of our findings which are positive on all counts; the full results will be given elsewhere. During the writing of this article a carbohydrate-polypeptide complex has been reported in *Ascophyllum*<sup>4</sup>, but the amino-acid composition of the polypeptide moiety has not been mentioned.

The plants we have examined are the freshwater green alga *Nitella opaca*, the green seaweeds *Cladophora* and *Chaetomorpha*, both with cellulosic walls, and *Codium*, a green seaweed with mannan walls<sup>5</sup>. Cell wall fractions were prepared by each of four methods. (1) The whole plant was thoroughly washed in distilled water and ground finely with a pestle and mortar. Mild centrifugation then yielded a crude cell wall fraction which was shaken with glass ballotini in water for up to 3 h in a Mickel shaker. The resulting homogenate was centrifuged at 1,000g for 1 min and the centrifugate was washed ten times in water and dried from acetone. This formed the standard method. On occasion the process was repeated several times until approximately constant weight and nitrogen content were achieved. (2) Cell wall fractions obtained by method (1) were shaken with glass beads in the protein solvents; phenol-acetic acid-water (1:1:1—w/v/v); phenol-ethanol (85 g:15 ml.); 50 per cent urea. Again, the process was repeated several times and with a combination of all three solvents. (3) With *Codium* the three solvents used in method (2) were

applied to material decolorized in *n*-butanol and acetone. (4) Methods (1) and (2) were applied to internodal cells of *Nitella* from which the bulk of the cytoplasm had been removed by mechanical pressure, and to specimens of *Chaetomorpha* from which the protoplasm had been ejected by sporulation. These, and particularly the latter, gave the cleanest wall fractions. Contamination of the material with glass powder as a result of repeated extractions is allowed for in the results presented.

The total protein content was determined in each case by Kjeldahl's method. Amino-acid analyses were made on cell wall fractions hydrolysed in 6 normal hydrochloric acid for 24 h and with the acid then removed in a vacuum desiccator; the amino-acids were dissolved in 0.1 normal hydrochloric acid containing 0.1  $\mu$ moles of norleucine, and 1 ml. aliquots placed on the column of a 'Technicon' automatic amino-acid analyser.

All the cell wall fractions contained protein (Table 1).

Table 1. KJELDAHL PROTEIN DETERMINATIONS

Sample	Method of preparation	Percentage protein (Kjeldahl)	Percentage protein (corrected for ash content)
Whole <i>Nitella</i>	(1)	8.3	10.3
(A, Table 2)	(2) (phenol-ethanol)	6.4	6.6
Whole <i>Nitella</i>	(2) (phenol-acetic acid-water)	6.8	—
Internodal cells, <i>Nitella</i>	(4)	5.1	7.8
<i>Chaetomorpha</i> (B, Table 2)	(1)	9.3	—
<i>Chaetomorpha</i>	(2) (phenol-ethanol)	7.3	—
<i>Codium</i>	(1) (one extraction)	8.9	—
"	(1) (two extractions)	6.4	—
" (C, Table 2)	(1) (nine extractions)	2.6	5.4
"	(2) (phenol-ethanol)	5.2	6.0
"	(2) (phenol-acetic acid-water)	5.7	6.1
"	(3) (50 per cent urea, one extraction)	8.0	—
"	(3) (50 per cent urea, three extractions)	2.9	5.2

With *Nitella*, extraction with water, phenol-ethanol, or phenol-acetic acid-water all left uniformly a wall fraction with a protein content lying between 6.5 per cent and 10 per cent. With *Codium* little change occurred either in wall yield or in protein content between the sixth and ninth water extract, and three extractions with 50 per cent urea gave a yield and a protein content similar to that after nine extractions with water; the yield of 5 per cent to 6 per cent protein is almost certainly the true wall protein value for this alga. With the exception of *Nitella*, 4-hydroxyproline was found in all wall hydrolysates (Table 2). A protein with characteristics resembling that

found in higher plants certainly occurs, therefore, in some algae. Of the other plants examined, *Cladophora* and *Chaetomorpha* contain less, and *Codium* very much more, hydroxyproline than do many of the higher plants so far reported<sup>1</sup>. With *Codium*, hydroxyproline formed the most abundant amino-acid in the protein. More significantly, in view of current suggestions as to the role of this protein, all cell wall fractions showed a peak in the position of cysteic acid, most prominent (Table 2) with *Nitella* wall fractions from which hydroxyproline is absent. The derivation of this peak from cystine was demonstrated in the walls of sporulated *Chaetomorpha* by hydrolysis under nitrogen, when the cysteic acid peak was reduced from 65 residues/1,000 to 1 residue/1,000 and cystine came off the column at a later stage.

Table 2. AMINO-ACID COMPOSITIONS OF VARIOUS ALGAL FRACTIONS

Peak 1	—	14	21	12	23	16	2

nd, Not determined.

In addition to the amino-acids already recognized for the wall protein of higher plants, several peaks were observed with these algae which seem not so far to have been recorded. In all cell wall fractions of *Cladophora*, *Chaetomorpha* and *Codium*, a double peak (peak 1, Table 1) came off the column in the basic region immediately before ornithine and lysine, in the same position, and with the same characteristics, as hydroxylysine—another amino-acid found in collagen but not in higher plant walls under tissue culture<sup>1</sup>, or in Douglas fir xylem<sup>6</sup>. The double peak seems to be due to the presence, in varying proportions, of two isomers of hydroxylysine as evidenced by the observation that, when cell wall hydrolysates are run on the column with added hydroxylysine, the double peak occurs in identically the same position but enlarged. Two other peaks, as yet not identified with certainty, came off the column after cysteic acid. These are distinguished by the feature that, after reacting with ninhydrin, the material of these peaks absorbs light more strongly at 440 $\mu$  than at 570 $\mu$ , as with proline and hydroxyproline. There is, therefore, the faint possibility that these peaks represent two isomers of 4-hydroxyproline. The peaks also occur in the water-soluble cytoplasmic fraction of *Codium*.

The presence of protein in sporulated plants of *Chaetomorpha*—yielding certainly the cleanest wall fraction of any investigation made of this kind—and the very similar amino-acid composition of the proteins from these plants and from all the other wall fractions dealt with here, seem to us to yield exceptionally good evidence that the protein involved is a wall-bound protein as claimed for higher plants<sup>1</sup>. This is further supported by the observa-

tion that, with *Chaetomorpha*, the wall protein content derived by a summation of all the amino-acids present is  $8.2 \pm 0.6$  per cent, closely similar to the figure yielded by the Kjeldahl estimate (Table 1). As a further check on this point, the cytoplasmic proteins of *Codium* (supplied by Dr. W. Mackie of this Department) were analysed and the analysis is recorded in Table 2. In these proteins the hydroxyproline content is very much less than in the wall protein (26 residues/1,000 as against 108 residues/1,000), the double peak tentatively credited to hydroxylysine is virtually absent (2–3 residues/1,000 at most), and the two unidentified fractions absorbing strongly at 440 $\mu$  are very much reduced. This seems to rule out any remaining possibility that the wall protein represents contamination of the wall by cytoplasmic proteins.

Table 3. PERCENTAGES OF TOTAL AMINO-ACIDS IN THE TWO UNIDENTIFIED PEAKS

	<i>Nitella</i>	<i>Chaeto- morpha</i>	<i>Clado- phora</i>	<i>Codium</i> (wall)	<i>Codium</i> (cytoplasm)	Carrot culture
Peak 2	3.7	1.0	0.9	3.3	0.3	0.05
Peak 3	—	0.2	1.5	6.2	0.9	0.05

We regard it, therefore, as established that proteins of the type considered to occur in the walls of higher plant cells are not confined to higher plants, with the corollary that any part played by wall proteins in cell growth may well be a general phenomenon. The absence of 4-hydroxyproline from *Nitella* wall protein is not at the moment to be regarded as of any great significance, because this amino-acid seems to be more remarkable as a convenient distinguishable label for wall proteins than for any particular function ascribed to it. Greater significance attaches to the presence in all wall hydrolysates of cysteic acid almost certainly derived, during extraction (and proved so with *Chaetomorpha*), from cystine. If it is true, as suggested, that S-S bonds are involved in wall extensibility, then these algae provide much more favourable material on which an estimate of their importance may be based than do almost any cells of higher plants. This has given impetus in this laboratory to an investigation of the tensile properties of walls of growing cells in the algae discussed in this article, which is now proceeding. The known effects of ions, of auxins, and of other exogenous materials or environmental conditions on both the growth rates of cells and the tensile properties of their cell walls lead us to suspect that S-S bonds are not the only bonds to be effective. The indications are, however, that the factors controlling cell wall expansion are more complex than envisaged by considerations confined to inter-carbohydrate bonding only. In particular, it is satisfactory to find a protein associated with the walls of *Codium* in which not only is the structural polysaccharide a mannan but in which virtually no polysaccharide other than mannan and a little glucan can be detected, because this plant and the other seaweeds known to have similar walls<sup>5</sup> demonstrate that no concept of a wall growth process based entirely on the carbohydrate architecture of cellulosic walls can possibly of itself be universal.

We thank Dr. G. N. Graham of this Department for instructing one of us (E. W. T.) in the use of the amino-acid analyser, and for bringing to our notice the possible significance of the double peak.

## PLANETARY SCIENCE

### Forecasting of Earthquakes—Correlation between Deep Foci and Shallow Events in Melanesia

In the Solomons Region of the S.W. Pacific, the deep focus earthquakes which have been detected since 1912 have been concentrated at the north-western end of the Bougainville-New Ireland, and in a region to the south-east of the Santa Cruz Group. Recent research has established a *prima facie* case for a systematic time-space correlation between deep foci and sequences of shallower seismic events similar to that found in the New Hebrides by Dr. Claude Blot in the course of several years of detailed investigation of thousands of seismic and volcanic events.

Beyond the Western Solomons deep focus region, and a little to the east, five separate deep shocks have been located beneath the New Georgia Group. If these are ignored, a distance of 1,600 km separates the two main regions of known deep focus shocks (Fig. 1, heavy stipple on map).

The structural picture which is revealed from the seismic zone in plan and longitudinal section along the island chain (to the same scale) is of considerable interest. In the map and section shown, the vertical interval equals the horizontal interval; deep foci take the form of two broad abutments at different depths which support a narrowing arch of seismicity along which phenomena travel upwards towards the centre in the San Cristobal area. If we consider the seismicity since 1963, the year when epicentres could be plotted more accurately because of the U.S.C.G.S. World Wide Standard Stations, then on the western side of the arch, the deepest intermediate foci occur at a shallower depth (about 250 km) than those on the eastern side of the arch (about 300 km). It will be

noted that generally the deep foci themselves also occur at a shallower depth in the west than in the east—about 450 km compared to 625 km.

The zone of apparent seismicity for 1963–66 has been lightly stippled on the map (Fig. 1). The seismicity for any one year shows (a) only a few deep foci in the west and in the east; (b) a greater number of intermediate shocks; (c) very many shallow shocks; density of earthquakes increases from the depths to the surface.

The almost complete absence of shocks between the deep foci and the deepest intermediate depths (250 km in the west, 300 km in the east) is notable, yet Blot's research in the New Hebrides had led him to postulate that there is a time-space correlation between deep foci and the shallower events, both for earthquakes and volcanic eruptions<sup>1</sup>. This has now been established for the Solomons as well. Blot and Grover used the hypothesis to predict volcanic eruptions some months before the event in the New Hebrides, Santa Cruz, and Solomon Islands<sup>2</sup>. Because of the difficulty of applying the method without the use of computers, as yet it has not been widely used. A complete list of these forecasts of eruptions is now being prepared in readiness for the I.U.G.G. meetings in Trieste and Zurich in 1967. The list includes the warning of the impending eruption of Tinakula in the Santa Cruz Group, quiescent for a decade, and that of Gaua in the New Hebrides, quiescent probably for centuries. The main difficulty in this region is the obtaining of reliable reports from these remote volcanic islands which do not possess radio communication.

It appears that deep focus shocks initiate thermo-energetic phenomena which radiate upwards along tectonic zones and trigger shallower earthquakes of the same order of magnitude as the deep shock, except where phenomena converge. The delays between a deep-shock and its related earthquakes are a function of the distance from, and the magnitude and depth of the deep shock. Convergence of thermo-energetic phenomena produces greater earthquakes. Their approximate epicentres may be predicted graphically by the intersection of the depth curves of time-epicentral distance graphs while their approximate dates of occurrence depend on the triggering depth (that is, the depth of the point of maximum concentration of energy) and may also be predicted graphi-

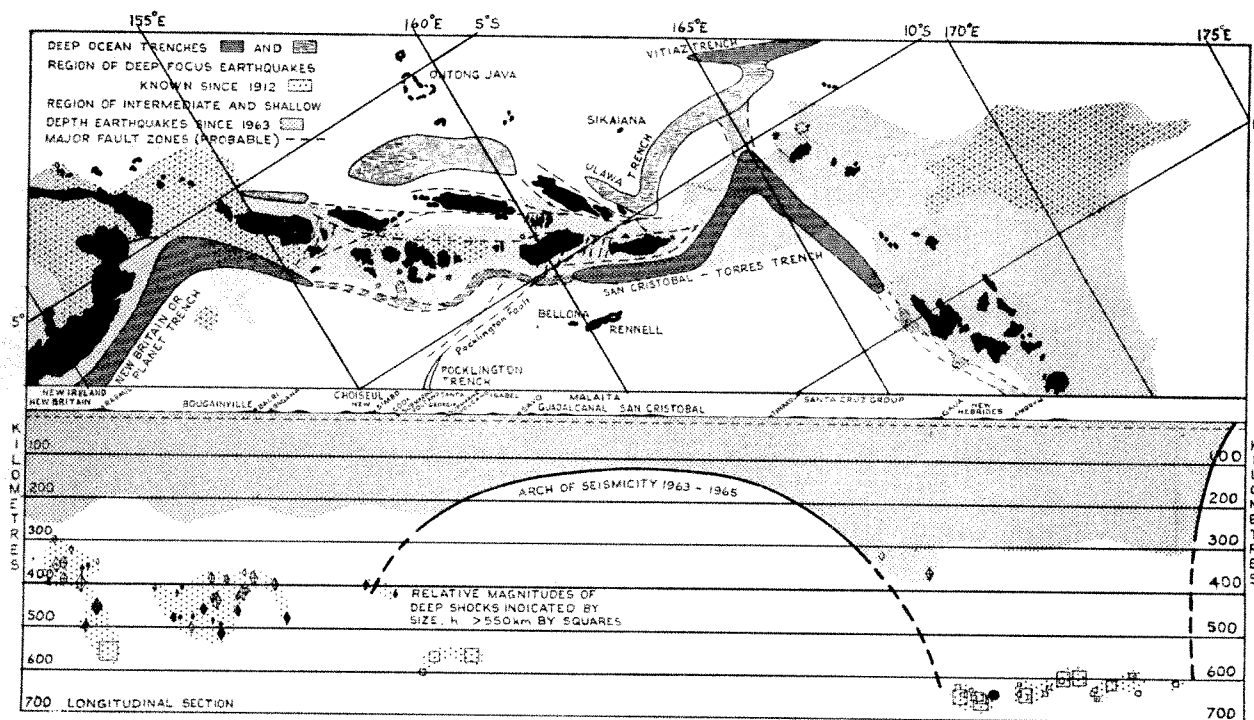

Fig. 1.

cally. The greatest magnitude earthquakes are caused by the convergence of thermo-energetic phenomena from deep shocks of great magnitude.

This would appear valid for all earthquakes in the Solomons region since 1963, and the data of the shocks triggering the important seismic crisis of June 15, 1966 (including two shocks of mag. 7+PAS) and that of December 31, 1966, in the Santa Cruz Group (also two shocks of mag. 7+) fit the theoretical hypocentres.

It should be noted that in this hypothesis deep events are considered which occur two and three years before the movement of surface faults. In the Solomon Islands gravity, magnetic, geological and bathymetric data, and recent movement, point to the existence of megashears; unfortunately, these occur mostly under the sea, and are only now being confirmed by the expedition by the Hawaii Institute of Geophysics. One fault with a vertical displacement of 2,000 m in the sea east of Malaita was reported by Professor A. Malahoff and L. Kroenke on December 6, 1966. It has proved unnecessary to consider faulting in prediction of great earthquakes because faults appear to be the ultimate effect of deep-seated phenomena; nevertheless some of these shears appear to continue for hundreds of kilometres, and therefore must be very deep-seated. As the mantle is almost certainly very close to the surface in the Solomons (according to the 1963-65 gravity data) the principal features described must extend below the shallow crust into the mantle itself, in which nearly all the earthquakes appear to occur.

I thank Dr. C. Blot and Professor S. W. Carey for helpful discussion.

### Third Brine Pool in the Red Sea

DURING the autumn of 1966 the R.V. *Chain* (cruise number 61) discovered a third area of hot, highly saline water in the rift valley of the Red Sea where two areas of similar water had previously been reported<sup>1-3</sup>. The two known areas, now called the Discovery Deep (21° 17' N., 38° 02' E.) and Atlantis II Deep (21° 21' N., 38° 04' E.), have salinities of about 255 parts per thousand and temperatures of 44° and 56° C respectively (refs. 2-4, and footnote (†) to Table 1). This communication describes the dimensions and characteristics of a third hole (Chain Deep, 21° 17' N., 38° 03-5' E.) and its relationship to the other two areas.

The third brine pool was discovered during a survey of the rift valley between the Atlantis II and Discovery Deeps. About fifteen traverses were made of this area to determine if the Atlantis II and Discovery Deeps were in direct communication. The survey shows a saddle crossing the rift valley with a narrow elongated trough on the eastern side of the saddle. The deepest part of this trough is at 2,066 m. Because the higher temperatures and salinities in the Discovery and the Atlantis II holes start around 2,000 m, it was important to determine if hot water was also present in this new deep. A temperature telemetering pinger, which was used to test all deep holes on R.V. *Chain*, was lowered at the position shown in Fig. 1. A maximum temperature of 34° C was recorded at a depth of 2,042 m (Fig. 2). Water samples, taken on the same lowering, had a maximum salinity of 74.2 parts per thousand at a depth of 2,024 m (Table 1). The increase in temperature and salinity accompanied by a marked decrease in oxygen is characteristic of the water in the other two deeps and defines the Chain Deep as a third brine pool. Unfortunately the deepest part of the hole was not

tested. Attempts to core the Chain Deep with both free fall and a 'Kasten' corer were unsuccessful.

Data from a depth recorder (Fig. 3) show the Chain Deep to be a narrow rift with slopes as high as 20°. Its length as defined by the 2,000 m contour interval is about 2.6 km and its maximum width is 0.7 km. The floor of the Chain Deep is V-shaped and more irregular when compared with the flat floored areas of the other two deeps.

The Chain Deep is separated from the Discovery Deep by a sill at 1,980 m, which is sufficiently high to prevent exchange of hot water between these two holes. The shallowest area observed between the Atlantis II and Chain Deeps is 2,009 m. If this is the shallowest area, exchange of hot water between the Atlantis II and Chain Deeps is possible. Temperature profiles from the three hot holes (Fig. 4), however, show distinct differences which suggest that the hot waters of the three holes are not in

Fig. 1. Bathymetry of the Chain Deep. Depth contours in metres corrected for sound velocity. Relative positions determined by radar fixes on an anchored buoy. Dotted lines indicate control.

Fig. 2. Precision Graphic Recorder record of the temperature telemetering pinger lowering into the Chain Deep. The pinger emits two pulses within a 1-sec interval. The first pulse ( $P_1$ ) is emitted every second, a following pulse ( $P_2$ ) is emitted after the first by a period of time that varies with temperature.  $B_1$  and  $B_2$  are the bottom returns from the two pulses. The distance between a pulse and its bottom return indicates the depth of the instrument above the bottom. Going from left to right in the figure,  $P_2$  shows several jumps which do not indicate a step-like pattern in the temperature distribution but are caused by stopping and starting of the winch. The accuracy of the instrument is  $\pm 1.25^\circ \text{C}$ . In the upper right-hand corner the pinger has reached the bottom and a temperature of  $34^\circ \text{C}$  is indicated.

Table 1. GENERAL HYDROGRAPHIC DATA FROM THE CHAIN DEEP

Corrected depth (m)	Temperature (°C)	Salinity (parts per thousands)	Oxygen (ml./l.)
1,730	21.94	40.63	2.15
1,830	21.97	40.63	2.19
1,930	22.06	40.88	2.19
1,999	23.80	42.01	1.52
2,013	22.0*	—	—
2,018	22.2	—	—
2,019	25.98	55.6†	0.15
2,021	23.0	—	—
2,024	29.07	74.2	0.10
2,025	25.0	—	—
2,029	28.4	—	—
2,031	32.2	—	—
2,037	33.0	—	—
2,042	34.0	—	—

\* Temperature values without salinity or oxygen measurements are selected measurements from the temperature telemetering pinger lowering (Fig. 2). Differences in depth for a given temperature as determined from the depth recorder and the reversing thermometers may be the result of many causes, one of which is the increase in the speed of sound caused by the increased temperature and salinity. This would make the true depths greater than the recorded depths. Normal Mathews corrections for the Red Sea were applied.

† The ionic ratio of these highly saline waters is different from that expected from evaporation of normal sea water. Thus the salinity values should be accepted only as an approximation. Chlorinity values for the Discovery Deep have been calculated by Brewer<sup>2</sup> to be about 155.5 parts per thousand and for the water at 44° C and for the Atlantis II Deep by Miller<sup>3</sup> to be about 155.5 parts per thousand for the 55.9° C water.

direct communication at present. This implies that a sill shallower than 2,009 m exists between the Atlantis II and Chain Deeps.

Temperature profiles obtained in the three holes with the telemetering pinger are shown in Fig. 4. The curves for the Atlantis II and Discovery Deeps are similar in general shape to those reported by Krause and Ziegenbein<sup>5</sup> using a continuous temperature recorder. The curve for the new Chain Deep shows a rapid increase in temperature from

about 21° to 32° C in the same depth range (2,020–2,030 m) where the Discovery and Atlantis II waters reach their highest temperature.

We do not believe that the three holes are now in direct communication because of the distinct differences in temperature profiles and the presence of the sills. The similarities in high temperature, high salinity, and low oxygen suggest, however, that the hot water in the three holes has a similar origin—either from the same source or by the mixing of hot water between the holes at some time in the recent past.

We thank F. C. Allstrom for preparation of the bathymetric map, and C. D. Densmore, R. G. Munns and R. L. Stanley for the hydrographic data. This work was supported by a grant from the U.S. National Science Foundation.

### Thermal Conductivity of Lunite as Dependent on Temperature

It has already been pointed out<sup>1,2</sup> that the value of the midnight temperature of the lunar surface  $T_n = 100^\circ \text{K}$  (ref. 3) is in conflict with the precision measurements of the constant radiotemperature component averaged over the disk. In fact, for  $T_n = 100^\circ \text{K}$  the constant component of the surface temperature at the disk centre<sup>1</sup> is equal to

$$T_0(0) = 219^\circ \text{K} \quad (1)$$

On the other hand, the constant component of the effective temperature measured over the disk for  $\lambda = 3 \text{ cm}$  is equal to  $T_{e0} = 212^\circ \pm 2^\circ \text{K}$  (ref. 1) and corresponds to the temperature at a depth of about 50 cm, where temperature increases by  $2^\circ$  at the most as a result of heat flow from the Moon's interior. Thus the constant component caused by solar heating alone at this depth, averaged over the disk, must be equal to

$$T_{e0} = 210^\circ \pm 2^\circ \text{K} \quad (2)$$

The effective temperature averaged over the disk is related to the constant component of the true temperature for the disk centre by the expression<sup>4</sup>

$$T_{e0} = (1 - \bar{R}) 0.964 T_0(0) \quad (3)$$

where  $\bar{R}$  is the mean spherical coefficient of wave reflexion from the Moon's surface, and depends on the dielectric constant  $\epsilon$ .

For  $\epsilon = 1.5$ ,  $1 - \bar{R} = 0.95$ ; for  $\epsilon = 2$ ,  $1 - \bar{R} = 0.92$  (ref. 5). Thus the constant component of the surface temperature at the centre of the disk, as obtained from radio measurements, is

$$T_0(0) = \begin{cases} 229 & \epsilon = 1.5 \\ 237 & \epsilon = 2 \end{cases} \quad (4)$$

Comparison with (1) reveals that the foregoing constant component is superior by

$$\Delta T = 10^\circ \div 18^\circ \quad (5)$$

to that obtained at the surface by infra-red measurements. I think that the discrepancy observed is caused by the existence of a real difference in the constant com-

Fig. 3. Precision Graphic Recorder record of a crossing of the Chain Deep.

Fig. 4. General temperature distribution in the Atlantis II (---), Discovery (· · · ·) and Chain (—) Deeps. Data obtained by temperature telemetering pinger lowerings made during Chain cruise 61.

ponent at the surface and at the 50 cm depth, which is not related to a flow of heat from the interior. This difference is possible<sup>7</sup> if the thermal conductivity and thermal capacity of lunite are dependent on temperature.

As is known, the temperature dependence of thermal conductivity is mainly related to a transfer of radiation energy. In a porous body the latter may take place even in a substance which strongly absorbs radiation by transfer through the pores. In that case the radiation component of thermal conductivity will be

$$K_s(T) = 4\sigma \frac{A}{2-A} T^3 S l_p \quad (6)$$

where  $\sigma$  is the Stefan-Boltzman constant,  $A$  is the emissivity of the material,  $l_p$  is the size of a pore,  $S$  is the proportional area occupied by pores. In the case of a radiation which penetrates through the substance the radiation thermal conductivity is

$$K_s(T) = \frac{16}{3} \sigma \epsilon_i T^3 \bar{l}_\lambda$$

where  $\epsilon_i$  is the dielectric constant of the substance for infra-red waves,  $\bar{l}_\lambda$  is the average mean-free quantum path for all frequencies (Rossel and mean).

$$\bar{l}_\lambda = \frac{\int_0^\infty l_\lambda \frac{dB}{dT} d\lambda}{\int_0^\infty \frac{dB}{dT} d\lambda} \quad (7)$$

where  $B_\lambda$  is Planck's function.

The theory admits that for dielectrics in the infra-red range  $l_\lambda = a\lambda$  as in the radio range. Thus if this is substituted in (7) we obtain

$$\bar{l}_\lambda = a \frac{0.36}{T} \quad (8)$$

This gives a square dependence of the radiation thermal conductivity on temperature

$$K_s(T) = 2 \sigma \epsilon_i a T^2 \quad (9)$$

The total thermal conductivity will be equal to the sum of the molecular  $K_0$  and radiation  $K_n$  ( $n = 2, 3$ ) thermal conductivities

$$K(T) = K_0 + K_n \quad n = 2, 3 \quad (10)$$

where  $K_n$  is found from formulae (6) and (9).

Taking (10) and the specific heat dependence in the form of  $C(T) = C_1 T$ , thermal conditions were computed for a homogeneous model. An increase of the constant component for a given  $\gamma(T) = (K_0 C)^{-1}$  was found to be dependent on the ratio of the radiation to the molecular component of the thermal conductivity  $K_n/K_0$ . This ratio can best be characterized by its value at temperature  $T_k = 300^\circ \text{K}$ . As revealed by computations on an electronic computer, for  $\gamma(300) = 600$  an increase of the constant component of the temperature  $\Delta T = 15^\circ \text{K}$  is possible, if

$$K_s(300) = 0.4 K_0 \quad (11)$$

or

$$K_s(300) = 0.25 K_0 \quad (12)$$

For  $\gamma(300) = 600$ ,  $C(300) = 0.2$  and lunite density  $\rho = 1$  the value of the molecular thermal conductivity  $K_0 = 10^{-5} \text{ cal cm}^{-1} \text{ sec}^{-1} \text{ deg}^{-1}$ . Comparing (12) and (6) for  $T = 300^\circ \text{K}$  we obtain the effective size of pores  $S l_p = 170 \mu$  ( $A = 1$ ). For the 50 per cent porosity  $S \approx 0.5$  the actual size of pores will be

$$l_p = 350 \mu$$

A similar value for pore size was derived in ref. 8 and in ref. 9, where the radiation component of thermal con-

ductivity was determined from the character of temperature variation at the Moon's surface at sunset.

Comparing (11) and (9) we obtain for  $\epsilon_i = 1.4$  that  $a = 13$ . This gives the depth of penetration of infra-red waves into lunite

$$l_\lambda = 13 \lambda \quad (13)$$

It is interesting to note that for radiowaves within the  $0.1 \text{ cm} \leq \lambda \leq 10 \text{ cm}$  range the relationship  $l_\lambda = 26 \lambda$  (ref. 1) holds for the depth of penetration into lunite. According to (8) an average depth of penetration for  $T = 300^\circ \text{K}$  is about  $170 \mu$ . It is worth noting that a quantity of a similar order ( $150$ – $250 \mu$ ) is obtainable from the measurements in the case of certain terrestrial rocks with grains of the order of  $70 \mu$  and less<sup>10</sup>. This testifies to a pretty high validity of expression (13). As pointed out earlier, the low thermal conductivity of lunite is evidence of the fact that the pores are not closed and are formed of gaps in solidly interconnected particles. The area of contact of a particle, as revealed by computations<sup>11</sup> should be much less than the grain area. The newly obtained data favour a conclusion that the lunite pores may not exceed  $350 \mu$ . For a porosity of 50–70 per cent lunite the pores and the particles must be approximately equal in size. Then in the case of a non-transparent substance the particles may not exceed  $350 \mu$ . A smaller size of pores is possible if the base substance is transparent to infra-red waves. In that case, for the aforementioned porosity of lunite half the infra-red quantum path will coincide with the total length of pores and the other half with the total thickness of transparent particles. The number of penetrated particles may not at any frequency be less than one, consequently its size will not exceed  $0.5 \bar{l}_\lambda = 80$ – $100 \mu$ . The particle size in that case is most likely to be of the order of the infra-red wavelength, that is  $10$ – $20 \mu$ .

I thank Boris Konstantinov, who suggested that I should study the effect of radiation heat transfer in lunar matter.

## THE SOLID STATE

### Hydrogen Isotope Diffusion

HYDROGEN isotope diffusion in metals and polymers has generally been treated in the literature as a single body problem with the motion of the hydrogen regarded as the important parameter. On this basis the equation for interstitial diffusion of hydrogen atoms in metals or molecular diffusion in polymers follows an equation of the form

$$D = \frac{v}{6} \frac{Ed^2}{RT} \exp(-E/RT) \quad (1)$$

where  $D$  is the diffusion coefficient,  $v$  a frequency which corresponds to the vibration of the atoms or molecule in

the solvent lattice,  $d$  the distance traversed in an elementary displacement and  $E$  the diffusional activation energy<sup>1</sup>. For the single body approximation,  $v$  is inversely proportional to the square root of the isotopic mass since hydrogen is much lighter than the molecules or atoms with which it interacts, so that

$$D_H/D_D = 2 \frac{E_H}{E_D} \exp(E_D - E_H)/RT \quad (2)$$

The temperature effect on the diffusion coefficient ratio for the hydrogen isotopes is negligible both for polymer systems<sup>2</sup> and metals<sup>3-6</sup> as would be expected from equation (2), because the H<sub>2</sub>-polymer and individual metal-H bonds are weak and will have small zero point energies, so that  $E_H \approx E_D$ . Thus the single body approximation leads to the conclusion that the ratio  $D_H/D_D$  should have a value close to 1.4 as has been found in some strongly interacting metal hydrogen systems, namely, palladium-hydrogen<sup>7</sup> and zirconium-hydrogen<sup>8</sup>. For polymer systems and a number of metals studied recently by myself and my colleagues, this has not proved to be the case, however, as shown in Table 1. We can only conclude that for these systems the motion of solute molecules or atoms in the solvent lattice is not rate controlling and that the diffusion rate is dependent on the solvent lattice itself.

Table 1. ISOTOPE EFFECTS ON DIFFUSION AND SOLUBILITY OF HYDROGEN

Material	Temperature range (°C)	$D_H/D_D$	$D_H/D_T$	$S_H/S_D$	$S_H/S_T$
Epoxy resin <sup>2</sup>	25-55	0.96 ± 0.06		1.16 ± 0.1	
Araldite <sup>2</sup>	20-40		1.01 ± 0.04		1.18 ± 0.07
Neoprene <sup>10</sup>		1.04 ± 0.10	1.07 ± 0.07	1.03 ± 0.14	1.02 ± 0.12
Maraged steel <sup>3</sup>	150-250	0.87 ± 0.07		1.44 ± 0.12	
En 58E steel <sup>4</sup>	250-400	0.99 ± 0.07		1.38	
Nilo-K <sup>5</sup>	200-350	0.96 ± 0.06		1.39 ± 0.08	
SAE 4130 <sup>9</sup>	—	1.14			
S110 steel <sup>6</sup>	250-400	1.17 ± 0.06			
Palladium <sup>7</sup>	200-300	1.31			
Zirconium <sup>8</sup>	—	1.50			

The motion required of the lattice atoms will be much less than that for self diffusion of solvent material and will clearly depend on solute molecule size, which is, of course, the same for hydrogen and deuterium within close limits. Furthermore, whether lattice motion or hydrogen molecule or atom motion are rate controlling will depend on a number of factors such as temperature, solute-solvent interaction and solvent material. The exothermic occluders—palladium<sup>7</sup> and zirconium<sup>8</sup>—with strong hydrogen atom-metal interaction, give large isotope effects on the diffusion coefficients. This shows that interstitial diffusion with hydrogen atom transport as the rate controlling step applies for these systems, while some steels<sup>6,9</sup> appear to be intermediate in behaviour (Table 1).

## Carbon Fibres of High Strength and High Breaking Strain

SOME details have recently been given about carbon fibres with high strength and high modulus produced at the Royal Aircraft Establishment (R.A.E.), Farnborough<sup>1</sup>, and by Rolls Royce, Ltd.<sup>2</sup>. Carbon fibres with average tensile strengths ( $\sigma_B$ ) of 250–300 × 10<sup>8</sup> lb./in.<sup>2</sup> and Young's moduli ( $E$ ) of about 60 × 10<sup>6</sup> lb./in.<sup>2</sup> have been reported, and this makes them extremely promising as a means of reinforcing plastics and metals. The purpose of this communication is to report that fibres with much higher strengths but with lower  $E$  and consequently higher breaking strains ( $\epsilon_B$ ) can be produced by means of a suitable heat treatment. The way in which  $E$  and  $\sigma_B$  of the R.A.E. carbon fibres vary with the heat-treatment temperature used is shown in Fig. 1. Each point on the graphs represents an average value obtained from twenty fibres tested with a tensile test machine at a strain rate of 0.05 cm/min.

For applications where fibres of high  $E$  are required it can be seen that heat treatment at a temperature of 2,500° C or more is necessary. On the other hand, when fibres with maximum  $\sigma_B$  and  $\epsilon_B$  are needed, the optimum heat-treatment temperature is only 1,500°–1,600° C. The highest  $\epsilon_B$  is 1.3 per cent, occurring as a result of heating to 1,500° C. This is more than twice the  $\epsilon_B$  of 0.6 per cent found for fibres of high  $E$  heated to 2,500° C. The strength distribution for fibres heated to 1,500° C is shown in Fig. 2, the  $\sigma_B$  for this sample being 444 × 10<sup>8</sup>

Fig. 1. Effect of heat-treatment temperature on the mechanical properties of carbon fibres at room temperature.

Fig. 2. Histogram of tensile strengths of carbon fibres after heat-treatment to 1,500° C.

lb./in.<sup>2</sup>. Thus carbon fibres have been made with  $\sigma_B$  higher than the value of  $250 \times 10^3$  lb./in.<sup>2</sup> quoted for *E*-glass fibres in use and approaching the figure of  $500 \times 10^3$  lb./in.<sup>2</sup> given for virgin fibres<sup>3</sup>. They also have higher *E*, that is,  $34 \times 10^6$  lb./in.<sup>2</sup> as compared with  $12.4 \times 10^6$  lb./in.<sup>2</sup>.

In a similar study, Shindo<sup>4</sup> found no trace of an increase in  $\sigma_B$  of carbon fibres as the treatment temperature was increased over the range 1,000°–3,000° C, and his results for *E* and  $\sigma_B$  are much lower than those reported here, as can be seen from Fig. 1. He did find a slight maximum for *E* after a heat treatment at 2,000° C. No trace of such a maximum was found with R.A.E. carbon fibres; a decrease in *E* suggests a change in structure, for example, in preferred orientation, which would be unlikely to be produced by a higher treatment temperature. The reason for the reported decrease in *E* by Shindo is therefore obscure.

A further point is that the strengths of R.A.E. carbon fibres given in Fig. 1 were obtained using 5 cm gauge lengths. When tests were done using 1 cm lengths the  $\sigma_B$  for fibres treated at 1,500° C was found to be  $496 \times 10^3$  lb./in.<sup>2</sup>, that is, 12 per cent higher than obtained with 5 cm lengths. This is due to the scatter of fibre strengths, the chance of including a weak spot in the test-piece being less when using shorter lengths. The highest  $\sigma_B$  found for a fibre treated to 1,600° C was  $745 \times 10^3$  lb./in.<sup>2</sup> for a 1 cm length, one-quarter of the maximum  $\sigma_B$  measured by Bacon<sup>5</sup> for graphite whiskers.

At present there is no evidence to suggest that tensile failures are due to surface damage on the fibres and it is possible that flaws are present at grain boundaries within the fibres because they are polycrystalline<sup>1</sup>. With this in mind the fibre structures are now being studied using an ultra-microtome to obtain thin sections for electron microscopy.

The results shown here indicate that a wide range of carbon fibres can now be produced. It is thought that there will be many applications for both the high *E* and the high  $\sigma_B$  high  $\epsilon_B$  fibres. We thank Mr. C. Addison and Mr. D. Wright for their help with fibre testing.

## CHEMISTRY

### 1,2-Benzanthracene Derivatives in a Kuwait Mineral Oil

THE isolation of 1,2-benzanthracene and 4'-methyl-1,2-benzanthracene from a crystalline mixture of benzanthracene homologues, obtained from fractions of a Kuwait mineral oil by reaction with maleic anhydride, was described in an earlier communication<sup>1</sup>. We have now isolated another isomer from the mixture and identified it as 7-methyl-1,2-benzanthracene, and obtained some insight into the composition of the monomethylbenzanthracene fraction by gas-liquid chromatographic analysis.

Gas-liquid chromatography of the crude benzanthracene fraction showed that it was a mixture of benzanthra-

cene itself with mono- and di-methyl derivatives<sup>1</sup>, and this was confirmed by mass spectrometry which revealed that small amounts of tri- and tetra-methyl compounds were present as well. We were unable to separate the mono- or di-methyl fractions from the mixture by chromatography on alumina or silica gel, but a useful partial separation was achieved by countercurrent distribution between hexane and nitromethane. After eighty transfers a fraction (35 mg) consisting essentially of monomethylbenzanthracenes was obtained. After further purification by chromatography on alumina and crystallization of the picrate, it was fractionally sublimed in a stream of nitrogen, affording a number of fractions, one of which, on crystallization from ethanol-benzene, gave 7-methyl-1,2-benzanthracene as colourless plates, melting point 177°–180° C undepressed when mixed with an authentic specimen, melting point 182° C. The 8-trinitrobenzene complex formed orange-red needles, melting point and mixed melting point 169°–171° C (authentic melting point 173°–174° C; we found that C = 65.8; H = 3.8; N = 8.1 per cent. C<sub>22</sub>H<sub>17</sub>N<sub>3</sub>O<sub>6</sub> requires C = 65.9; H = 3.8; N = 9.2 per cent).

Because of the very small amounts of material available, and the complexity of the mixture, we were unable to achieve any further separation of pure constituents, and we were led to consider analysis of the mixture by gas-liquid chromatography. This technique has been used to analyse mixtures of polycyclic aromatic hydrocarbons of different types<sup>2</sup>, but there have been very few reports of its application to mixtures of methyl homologues<sup>3</sup> of the same hydrocarbon. We studied a number of systems employing both packed and capillary columns; the best results (Table 1) were obtained with a stainless steel capillary column coated with silicone gum, used in conjunction with a 'Perkin Elmer F11' instrument fitted with a flame ionization detector. Even under the most favourable conditions, however, only partial separation of a synthetic mixture of equal amounts of all the monomethylbenzanthracenes was achieved, the twelve isomers being resolved into five groups as shown in Table 2.

Table 1. GAS-LIQUID CHROMATOGRAPHY OF METHYL-1,2-BENZANTHRACENES

Compound	Retention time (min)	Relative retention time	Compound	Retention time (min)	Relative retention time
1,2-Benzanthracene	46.0	1			
1'-Methyl-	63.0	1.37	5-Methyl-	68.0	1.48
2'-Methyl-	63.0	1.37	6-Methyl-	65.3	1.42

9	97.3	2.17	6.0	—
10	102.0	2.28	12.6	—
11	106.0	2.37	5.6	6,7-dimethyl-

tography; increase in peak height was taken as evidence of identical retention time. The results confirm the complexity of the mixture of methylbenzanthracenes from the oil. It is evident that the 1', 2', 4-, 5- and 8-isomers together represent less than 10 per cent of the crystalline material examined; not all of these may be present, though the mixture undoubtedly contains some of them in small amount. At least two monomethyl derivatives are present in substantial amounts, but as many as five could be present to make up the two major peaks. It is of interest that the two isomers which have been isolated, the 4'- and 7-methyl compounds, fall one in each of the two major peaks. The parent hydrocarbon, which has also been isolated from the mixture, forms a third large peak. No peaks which correspond to the strongly carcinogenic 9- and 10-methyl isomers are found in the chromatograms, and this was confirmed by addition of authentic specimens of these hydrocarbons and re-chromatography, when peaks appeared at the expected positions. Later peaks are thought to be caused by dimethylbenzanthracenes, but could not be assigned because of lack of reference data.

Biological tests (private communication from Dr. D. L. Woodhouse, University of Birmingham) have shown that the extracts obtained from high-boiling fractions of the Kuwait oil by reaction with maleic anhydride, and subsequent regeneration from the acidic adducts, are carcinogenic. It is reasonable to suppose that the activity of these materials may be at least in part a result of their content of benzantracene homologues, some of which are potent carcinogens<sup>4</sup>, although none of the compounds so far isolated has more than marginal activity. Benzantracene derivatives, however, are evidently not the only type of carcinogen in the oil, for the bulk of the fractions which did not react with maleic anhydride were also strongly active (Woodhouse), and it was shown in model experiments using radioactive 1,2-benzanthracene that the carcinogenic activity of these materials could not be caused by residual amounts of benzantracene homologues which had not been removed by the maleic anhydride treatment.

### Membranes for measuring Low Molecular Weights by Osmotic Pressure

THE determination of molecular weight from measurements of equilibrium osmotic pressure using aqueous solutions has usually been limited to values greater than 15,000, although it is possible to measure molecular weights as low as 4,000 with ancillary measurements<sup>1</sup> using solute permeable membranes.

Membranes have recently been developed for the ultra-filtration of micro-solutes with nominal lower limits of molecular weights of 350, 1,000 and 10,000. These membranes are hydrous polymers and are described as the interaction product of polyanions and polycations. They have an ionically cross-linked structure and are sold under

the name of 'Diaplex' by the Amicon Corp., Cambridge, Massachusetts. It will be shown that these membranes are also very suitable for measuring molecular weight.

The osmotic pressures of some polyethylene glycol (PEG) solutions were measured using a Pinner-Stabin<sup>2</sup> osmometer fitted with 350 and 1,000 'Diaplex' membranes. The solvent was 0.3 normal potassium chloride containing 0.04 per cent octan-2-ol. The latter was used to suppress surface tension effects. All measurements were made at  $25^\circ \pm 0.01^\circ \text{C}$  and osmotic equilibrium was attained in 24 h if there was no diffusion of solute across the membrane.

The results for two samples of PEG are presented in Table 1. The manufacturer gives a molecular weight range of 950–1,050 for the PEG 1,000 (Shell Chemical Co.) and 3,000–3,700 for the PEG 4,000 (Union Carbide).

Table 1. MOLECULAR WEIGHT OF POLYETHYLENE GLYCOLS

Sample	Membrane	$M_n$	S.E.	Number of observations
PEG 4,000	350	3,070 $\pm$ 60		7
" 4,000	1,000	*3,880 $\pm$ 60		3
" 1,000	350	*1,360 $\pm$ 70		4

\* Obtained by extrapolation to zero time.

Equilibrium measurements were obtained with the 350 membrane and PEG 4,000. There was no systematic trend in the ratio of osmotic pressure ( $\pi$ ) to concentration ( $c$ ) when the concentration ranged from 0.02 to 0.1 g/100 g solution. The values of  $\pi/c$  could therefore be averaged for the calculation of  $M_n$  from  $RT\pi/c$ .

Results for the PEG 4,000 and the 1,000 membrane gave a higher average molecular weight because the membrane was slightly permeable to this solute, and the osmotic pressure decreased slowly with time. It was necessary to extrapolate the linear relationship of  $\log \pi$  to time to zero time to obtain the initial osmotic pressure. The further corrections described by Gardon and Mason<sup>3</sup> are clearly needed for this situation.

Solute diffusion was also observed when PEG 1,000 was measured in a 350 membrane and again corrections should be applied.

The values of  $\pi$  for a sample of polyvinyl alcohol of nominal molecular weight 80,000 depended on the concentration. A plot of  $(\pi/c)^{1/2}$  against  $c$  was extrapolated to zero concentration in accordance with the graphical method of Berghlund<sup>4</sup> (Fig. 1). A linear correlation coefficient of 0.977 was obtained and the intercept of the regression line showed a molecular weight of 82,200 with a standard error of 500.

'Diaplex' membranes are well suited to osmometry in aqueous solution because of their high permeability to water (10–100 times that of 'Cellophane') and low permeability to solutes even of quite low molecular weights,

Fig. 1. The regression line  $(\pi/c)^{1/2} = 0.919c + 5.55$  and the experimental points obtained for polyvinyl alcohol.  $\circ$ , 1,000 membrane;  $\bullet$ , 1,000 membrane and osmometer with the volume reduced by half with a stainless steel block;  $\square$ , 350 membrane and osmometer with reduced volume.

which allows a rapid attainment of equilibrium. Even where some permeability to solute is evident, if it is not too great, correction may be made by a simple extrapolation of the curve of the log  $\pi$  against time. The low molecular weight cut-offs of the membranes allow molecular weights as low as 3,000 to be measured by equilibrium methods. Values as low as 1,000 can be determined using extrapolation techniques provided the required corrections<sup>1</sup> are made.

### Electronic Spectra of the Allyl and $\beta$ -Methallyl Free Radicals in the Far Ultra-violet

THE electronic states of the free allyl radical

have been the subject of several theoretical investigations<sup>1</sup>. Longuet-Higgins and Pople<sup>2</sup> predicted that the lowest doublet excited states (<sup>2</sup>B<sub>1</sub>) should have energies of 2.74 eV (4520 Å) and 5.29 eV (2340 Å) above the <sup>2</sup>A<sub>2</sub> ground state. Although both electric dipole transitions are allowed, from the spatial electron distributions, the long wavelength system was predicted to be weak and the short wavelength system strong. Currie and Ramsay<sup>3</sup> have recently observed a weak system with a 0-0 band at 4083 Å in a variety of allyl compounds after flash photolysis. On substantial chemical evidence, this was assigned to the predicted long wavelength transition of the allyl radical.

The object of this communication is to report some experiments on the flash photolysis of olefines and some allylic compounds in the gas phase, which have revealed a new band system in the far ultra-violet with an intensity maximum at 2250 Å; combining chemical evidence with established photochemical mechanisms, it has been possible to conclude that the transition corresponds with the predicted short wavelength system of the free allyl radical. A number of investigators have detected absorption bands in the far ultra-violet in irradiated polyethylene which they have tentatively assigned to the allyl radical<sup>4-5</sup>. We also record here a new band system in the far ultra-violet region, observed in flashed compounds containing the  $\beta$ -methallyl group.

The flash photolysis apparatus was of standard design. With the photolysis lamp and reaction vessel constructed of 'Spectrosil' grade quartz, and with the volume contained by the reflector flushed out with nitrogen, photolysis occurred down to about 1600 Å. Hilger small, medium and Littrow quartz-prism spectrographs were used in various aspects of the work with flash energies from 300 to 3,000 J. Spectra were recorded on 'Ilford HP3' plates sensitized with sodium salicylate.

Fig. 1a shows a series of absorption spectra taken during and after flash photolysis of butene-1; in addition to the Herzberg methyl radical band<sup>6</sup> at 2160 Å, a strong system occurs in the 2200-2300 Å region. Because of the high intensity of the new bands they can conveniently be recorded with low flash energies of about 300 J, with a single optical pass. The same system has been observed in the flash photolysis of eight compounds containing the allyl group, including propylene. The spectrum was not observed in a variety of compounds not containing the allyl group. Although the spectrum is banded, there is an

underlying continuum from 2270 Å to shorter wavelengths. The long wavelength limit of the strong bands is 2310 Å; other faint bands were detected at wavelengths up to above 2400 Å. Lossing, Marsden and Farmer<sup>7</sup> used mass-spectrometry to investigate the mercury photosensitized decomposition of a number of hydrocarbons. The principal transients detected in butene-1 were the methyl and allyl radicals, while substantial yields of the allyl radical were also observed in propylene. Notwithstanding the established hazards of attempting to assign spectra without a rotational analysis, we consider that detection of the same bands from eight compounds containing the allyl group, taken with the theoretical energy and intensity prediction and the photochemical results of Lossing *et al.*, establishes rather conclusively that the carrier of the spectrum of Fig. 1a is the free allyl radical.

Fig. 1b is a series of absorption spectra taken during the flash photolysis of isobutene. In addition to the methyl band, a transient absorption appears in the 2300 Å to 2420 Å region, consisting of a progression of about eight broad and apparently diffuse bands, together with a pair of comparatively narrow bands at 2230 and 2250 Å. The bands appear to be due to a single carrier, because they show no significant variation in relative intensity either during their decay or from one parent molecule to another. In their investigation of the mercury photosensitized decomposition of isobutene, Lossing *et al.*<sup>7</sup> detected a high yield of the  $\beta$ -methallyl radical

We have detected the spectrum of Fig. 1b in the flash photolysis of four compounds containing the  $\beta$ -methallyl group, and consider that the  $\beta$ -methallyl radical is the carrier of the bands.

A curious feature of this work has been the detection of the free methyl radical in varying yields, not only from every compound containing the methyl group, but also

Fig. 1. a, Decay of allyl radical with time. 4 mm butene-1 + 100 mm argon. Flash energy = 320 J. b, Decay of methallyl radical with time. 0.5 mm isobutene + 100 mm argon. Flash energy = 1,608 J.

from allyl alcohol, diallyl ether, allyl amine, allyl bromide, allyl cyanide, diallyl, butadiene and ethylene. Hydrogen atom migration with subsequent scission of the C-C bond occurs with all the molecules in the latter group, though the overall quantum yield is generally small. Production of the methyl radical in flashed ethylene may be biphotonic. The observations do, however, provide direct evidence for the postulate that ethylidene participates in the photochemistry of ethylene<sup>8</sup>. We have not yet detected the CH fragment, and it is known to react very rapidly with ethylene (ref. 9 and J. R. McNesby, personal communication).

We thank Dr. C. L. Currie for several valuable discussions.

## PHYSICS

### Correction of Some Erroneous Calculations of the Einstein A Coefficient for the 18 cm Transition of OH

In a recent note<sup>1</sup> Turner pointed out the confusion over the value of the Einstein A coefficient for the  $^2\Pi_{3/2}$ ,  $J=3/2$ ,  $\Lambda$ -doublet transition of OH. This coefficient is required to derive the interstellar abundance of OH from the intensity of the OH absorption lines observed in radio astronomy. Turner points out an error in previous calculations which may be traced to an incorrect matrix element in equation (2-16) of Townes and Schawlow<sup>2</sup>. His own calculation, however, is also in error in some respects. The calculation of the transition probability can most conveniently be done in two steps. First the probability can be calculated for the pure  $\Lambda$ -doublet transition, without regard to hyperfine structure. Second, the effect of the hyperfine structure can be treated by well-known methods. The Einstein A coefficient for the  $\Lambda$ -doublet transition is related to the dipole matrix element  $\mu_{ij}$  by

$$A_{\Lambda} = \frac{64\pi^4\nu^3}{3hc^3} |\mu_{ij}|^2$$

where  $|\mu_{ij}|^2$  is given by<sup>3</sup>

$$|\mu_{ij}|^2 = \sum_{M'} |\mu_x(JMJ'M')|^2 + |\mu_y(JMJ'M')|^2 + |\mu_z(JMJ'M')|^2$$

The summation is carried out only over  $M'$ , since  $A_{\Lambda}$  represents the probability that a molecule in one particular state  $M$  of the upper level will make a transition to any state  $M'$  of the lower level. The dipole matrix element may be related to the line strength  $S_{ij}$  in the usual manner

$$|\mu_{ij}|^2 = S_{ij} \mu^2 (2J+1)^{-1}$$

where  $\mu$  is the permanent electric moment.  $S_{ij}$  is identical with the familiar symmetric rotor line strength<sup>4</sup> if  $K$  (the component of angular momentum along the molecular axis) is replaced by  $\langle \Omega \rangle$ ; we thus have

$$S_{ij} = \frac{(2J+1) \langle \Omega \rangle^2}{J(J+1)}$$

so that

$$|\mu_{ij}|^2 = \frac{\langle \Omega \rangle^2 \mu^2}{J(J+1)}$$

With the use of the most recent molecular constants of Radford<sup>5</sup>, which lead to  $\langle \Omega \rangle = 1.470$  and the accurate dipole moment ( $1.660 \pm 0.010 D$ ) of Powell and Lide<sup>6</sup>, we finally obtain for the  $^2\Pi_{3/2}$ ,  $J=3/2$  transition

$$A_{\Lambda} = 8.53 \times 10^{-11} \text{ sec}^{-1}$$

This result is just one-half the value obtained by Turner. The reason lies in the incorrect factor of  $2I+1$  which appears in his equation (4); the  $\Lambda$  doublet transition probability clearly cannot depend on the nuclear spin  $I$ . Turner's error comes from the fact that his definition of  $|\mu_{\Lambda}|^2$  in equation (2) is inconsistent with his equation for  $A_{\Lambda}$ . If he chooses to sum over all magnetic quantum numbers  $M_J$ ,  $M'_J$ ,  $M_I$ ,  $M'_I$  in equation (2), then the total statistical weight factor  $(2J+1)^{-1} (2I+1)^{-1}$  must appear in the definition of  $A_{\Lambda}$ .

We must now consider the effect of hyperfine structure. The apportionment of intensity among the hyperfine components can easily be found from the familiar formulas<sup>7,8</sup> or tables<sup>9</sup> for the weak coupling of two angular momenta. The result is that the hyperfine components should have intensities in the ratio 1:5:9:1 (assuming that thermal equilibrium applies), as previously given by several authors<sup>10,11</sup>. The relative intensities involve both a statistical weight and a transition probability factor, however, and it must be recalled that the principle of spectroscopic stability applies to the intensities, not to the Einstein coefficients. We can calculate the Einstein coefficient  $A_{FF'}$  for an individual hyperfine component ( $F \rightarrow F'$ ) in the following way. We first write the intensity  $I_{FF'}$  for emission from an upper level  $F$  to a lower level  $F'$  as

$$I_{FF'} = \alpha_{FF'} I_{\Lambda},$$

$$\sum_{FF'} \alpha_{FF'} = 1$$

where  $I_{\Lambda}$  is the total intensity of the  $\Lambda$  doublet transition and  $\alpha_{FF'}$  is the normalized relative intensity mentioned above (and listed in Table 1). Then in order to maintain the interpretation of the Einstein coefficient as a transition probability, we must define  $A_{FF'}$  as

$$A_{FF'} = A_{\Lambda} \alpha_{FF'} (\sum_F g_F) / g_{F'}$$

where  $g_F = 2F+1$  is the statistical weight of an upper hyperfine level. This leads to the values of  $A_{FF'}$  for the OH transitions shown in Table 1.

It may be noted that

$$A_{12} + A_{11} = A_{22} + A_{21} = 8.53 \times 10^{-11} \text{ sec}^{-1} = A_{\Lambda}$$

In other words, the probability that a molecule in one particular hyperfine sub-level of the upper  $\Lambda$  doublet level will radiate into one or the other sub-level of the lower  $\Lambda$  doublet level is identical with the basic transition probability  $A_{\Lambda}$ . This is expected, as the nuclear spin interactions cannot affect the net transition probability in this order of approximation.

Turner's calculation for the individual hyperfine components is basically correct because he has included the proper degeneracy factor,  $(2F+1)^{-1}$ , in his definition of  $A_{FF'}$ . Unfortunately, his numerical values are not consistent with his equations, although the difference is trivial for the two strong components.

A value of  $A_{22} = 2.66 \times 10^{-11} \text{ sec}^{-1}$  for the 1,667 Mc/s transition has been given by Barrett<sup>11-13</sup>. It seems likely that his calculation made use of the erroneous matrix element from Townes and Schawlow<sup>2</sup> (repeated by Dousmanis, Sanders and Townes<sup>14</sup>); his value should thus be

Table 1

Transition (in emission)	Frequency (Mc/s)	$\alpha_{FF'}$	$A_{FF'}$ (sec <sup>-1</sup> )
$F=1 \rightarrow 2$	1,612	0.0625	$1.42 \times 10^{-11}$
$F=1 \rightarrow 1$	1,665	0.3125	$7.11 \times 10^{-11}$
$F=2 \rightarrow 2$	1,667	0.5625	$7.68 \times 10^{-11}$
$F=2 \rightarrow 1$	1,720	0.0625	$0.85 \times 10^{-11}$

multiplied by  $(2J+1)/J=8/3$ . Also, he used<sup>13</sup> a slightly smaller value of the dipole moment of OH (1.60 D). When these corrections are made, Barrett's value of  $A_{22}$  becomes  $7.64 \times 10^{-11} \text{ sec}^{-1}$ , in good agreement with the value obtained here.

A still different value of  $A_{22}=0.964 \times 10^{-11} \text{ sec}^{-1}$  has been quoted by Goss and Spinrad<sup>13</sup>, without details of the calculation. It is noted that this is just 1/8 of the value obtained here, which suggests that their calculation of  $A_{FF'}$  omitted the factor  $\sum_F g_F=8$ .

## BIOPHYSICS

### Orientation of Collagen Fibres in Rat Dentine

It is well known that the dominant part of the organic matrix of dentine is collagen, the fibres of which are preferentially orientated. The accepted view is that the collagen bundles, apart from a narrow layer of "mantle dentine" formed first, lie predominantly in the plane of the mineralizing front, that is approximately parallel to the enamel-dentine junction, the pulpal surface and the incremental lines of growth<sup>1</sup>. The dentinal tubules tend to run at right angles to the incremental lines, so that sections transverse to the tubules show collagen bundles of the intertubular matrix lying largely in the plane of the section and sweeping at tangents to the tubules. In human dentine there is a "peritubular collagen-free zone"<sup>2</sup> which can be shown to become

Fig. 1. Ultra-thin section of incisor predentine stained with uranyl acetate. Both the odontoblast processes and most of the collagen bundles are cut transversely. Some collagen fibres, however, lie in the plane of the section. ( $\times c. 3,350$ .)

Fig. 2. The mineralizing front in developing molar dentine again showing the odontoblast processes and most of the collagen bundles cut transversely. Note the "peritubular collagen-free zones". Unstained. ( $\times 5,700$ .)

Fig. 3. Longitudinal ground section through rat lower molar cusps seen between crossed nicols. The dentinal fibres leave the enamel-dentine junction approximately at right angles but then bend abruptly to descend almost parallel to the long axis of the cusp. The dentine matrix in this area is birefringent, and appears green when the tubules are parallel with the slow (positive) axis of a quartz-sensitive tint. The collagen is therefore largely parallel to this tubule direction. ( $\times 60$ .)

hypermineralized with respect to the remainder of the matrix<sup>3</sup>. There is, however, some evidence that collagen exists in this peritubular zone and that the fibres<sup>4</sup> and the hydroxyapatite crystals<sup>5,6</sup> are arranged parallel to the long axes of the tubules.

During a study of the ultrastructure of developing coronal dentine in the molars and incisors of the rat it was observed that most of the collagen fibres were parallel to, rather than perpendicular to, the tubules (Figs. 1 and 2). Some tubules were observed in predentine with a peripheral zone  $1\mu$  wide which was relatively free from organized collagen, and some tubules in the calcified dentine were surrounded by a zone of greater electron density. This peritubular zone frequently accepts heavy metal stains more readily than the surrounding dentine, indicating a greater concentration of reactive ground substance.

Further information was sought by surveying a number of ground sections with the polarizing microscope. In most of the molar dentine the orientation of the collagen fibres is in accord with the accepted view. The steepness of the molar cusps, however, is such that the tubules in this area ascend along the long axis of the cusp and are almost parallel to the enamel-dentine junction for most of their course (Fig. 3). The dentine in this region is positively birefringent with respect to the long axis of

the cusp, and, since the birefringence of collagen predominates<sup>1</sup>, most of the fibres must also lie in this direction. This explains the appearance under the electron microscope of fibres lying along the tubules. In the incisor dentine it was deduced that collagen fibres, for the most part, lie perpendicular to the tubules and parallel to the incremental lines. A narrow band was seen in all sections immediately underneath the enamel where the birefringence differed from that of the rest of the dentine, indicating a collagen orientation more parallel to the tubules; this constitutes the layer of von Korff or "mantle dentine". Some teeth, however, had broad areas in the dentine nearer the centre of the tooth, in which the mean direction of the collagen fibres appeared to be at 40°–45° to that of the tubules and at 20°–30° to the incremental lines. Sections from such areas could give the electron microscope appearance referred to already.

Evidence from the molars thus supports the view that, as each increment of dentine is formed, the collagen is laid down in sheets of randomly interwoven fibres in the plane of the formative front and that the tubules are not involved in their orientation.

We thank Mr. M. S. Gillett for preparation of the ultra-thin sections and for the photography.

### Effects of Ultra-violet Microbeam Irradiation of Various Sites in HeLa Cells on the Synthesis of RNA, DNA and Protein

THERE have been a number of studies on the effects of ultra-violet microbeam irradiation of delimited areas within cells in culture. In experiments with mitotic cells<sup>1–10</sup>, it has been found that irradiation of a chromosome produces a loss of DNA and histone at the site of irradiation<sup>3,4,9</sup>, and also that the spindle diminishes in size or disappears temporarily following the irradiation of any part of the cell<sup>1,2,5–8,10</sup>. In experiments with interphase cells<sup>11,12</sup>, some authors have reported that about two-thirds of the labelling of cytoplasmic RNA is suppressed by nucleolar irradiation<sup>11</sup>, while extranuclear nuclear irradiation results in a progressive inhibition of DNA synthesis for several hours after the irradiation<sup>12</sup>. We have carried out an autoradiographic study on the effects of ultra-violet microbeam irradiation of different cellular sites on synthesis of RNA, DNA and protein in order to compare the pattern of inhibition in a single cell type.

For our experiments we used a standard HeLa cell line, which had been propagated as a cell-sheet on a glass surface. The cells were cultivated on a quartz coverslip in the culture medium and by a method of culture described previously<sup>9</sup>. The irradiation apparatus was of the Uretz type<sup>5</sup>, and the spot of the heterochromatic microbeam was about 2  $\mu$  in diameter in the focal plane. Each cell was irradiated at only one site for 25 sec unless otherwise indicated, using a high pressure quartz mercury arc lamp (Toshiba 80 W) as the irradiation source. At various times over a period of 12 h, or at 24 h after the irradiation, a group of the coverslip cultures was labelled for 30 min in a culture medium supplemented either

with 2  $\mu$ c./ml. <sup>3</sup>H-cytidine (specific activity: 2.02 c./mmole) or with 1  $\mu$ c./ml. <sup>3</sup>H-thymidine (specific activity: 8.6 c./mmole), or with 16  $\mu$ c./ml. <sup>3</sup>H-phenylalanine (specific activity: 441 mc./mmole). Autoradiographs were prepared by the method of Ficq<sup>13</sup>, using 'Kodak AR10' stripping film. The slides were exposed for 2 weeks and stained with Giemsa solution.

The irradiated cells were relocated on the autoradiographic slides using diagrams made at the time of irradiation, and were then photographed. The number of silver grains over the nucleolar, extranuclear nuclear and cytoplasmic areas was counted on the photographs and tabulated after making a correction for background. An estimate of the synthetic activity for each area in the irradiated cells was computed as a percentage of the average grain count for the corresponding area of unirradiated cells in the same fields.

Fig. 1. Effect of irradiation of one nuclear site on nuclear <sup>3</sup>H-cytidine labelling. ○, Nucleolar irradiation, nucleolar activity; ●, nucleolar irradiation, extranuclear nuclear activity; □, extranuclear nuclear irradiation, extranuclear nuclear activity. Figures in parentheses show number of experimental cells.

Effects of nucleolar irradiation on nucleolar and nuclear cytidine uptake are summarized in Fig. 1. In this experiment, cells bearing only a nucleolus were selected and the centre of the nucleolus was irradiated. Four to five hours after the irradiation, the mean activity of the irradiated nucleolus had increased from about 10 per cent to about 20 per cent of the activity in control cells, while that of the extranuclear area was restored to about 70 per cent after first showing a decrease to about 35 per cent 1 h after irradiation. These activities were further restored 24 h after irradiation. The form of the curve of the extranuclear nuclear side effect suggests that about 1 h is required for substance(s) produced at the irradiated site to diffuse throughout the nucleus and affect the enzyme systems in the rest of the nucleus. Irradiations at doses other than 25 sec showed similar patterns in the processes of inhibition and recovery. At lower doses the nuclear side effect was smaller, but the inhibition of the nucleolar activity was also reduced. At higher doses nucleolar inhibition was higher but the side effect was also greater and the recovery was slower. The maximum difference between the two effects was about 50 per cent and was obtained with an exposure time of 25 sec. Morphologically, a circular area bearing fewer grains was found in the nucleus around the irradiated nucleolus for several hours after the irradiation.

Effects of the nucleolar irradiation on the cytoplasmic

RNA were examined by a procedure of labelling with 0.4  $\mu\text{C}/\text{ml}$ .  $^3\text{H}$ -cytidine for 4 h starting 3 h after irradiation. These intervals were selected to measure the dependence of cytoplasmic labelling on nuclear and nucleolar inhibition during the stable stage following the first recovery period. In 15 cells with irradiated nucleoli, the mean of the percentage control activities of the extranucleolar areas of the nuclei was  $79.9 \pm 4.4$  per cent, while that of the cytoplasm was  $57 \pm 3.5$  per cent. There was no significant inhibition in the cytidine uptake, however, either in the cytoplasm of cells, the nuclei of which had been irradiated, or in the nuclei of the cytoplasm irradiated cells a few hours after the irradiation.

Effects of the irradiation on the labelling of the nucleus with thymidine were examined in the cells where either an extranucleolar nuclear area, or a cytoplasmic area, or all nucleoli in a cell, were irradiated with a total dose of 25 sec in different cells in the same fields. The results are summarized in Fig. 2. The irradiated cells without grains were excluded from the data. For all nuclear sites the irradiation caused an inhibition in the rate of DNA synthesis, which developed progressively for several hours after the irradiation. There appears to be no significant difference between the effects of the nucleolar and extranucleolar nuclear irradiations. These results are in good agreement with those obtained by Dendy and Smith<sup>12</sup> in their comparative study on the effects of ultra-violet and  $\alpha$ -particle microbeams on the inhibition of DNA synthesis in mouse fibroblasts. Our results for cytoplasmic irradiation differ from theirs, however, because their rate of the reduction of DNA synthesis was smaller. This might be caused by differences in the experimental conditions or the cell species used.

Fig. 2. Effect of irradiation on  $^3\text{H}$ -thymidine labelling. ○, Nucleolar irradiation; ●, extranucleolar nuclear irradiation; ○, cytoplasmic irradiation. Figures in parentheses show number of experimental cells.

In experiments on protein synthesis with phenylalanine incorporation, we found at most only a slight degree of inhibition for all irradiation sites, including nucleolar irradiation.

These results show that ultra-violet microbeam irradiation at one nucleolar or extranucleolar nuclear site rapidly caused an inhibition of RNA synthesis which is partly restored a short time after the irradiation. The inhibition of DNA synthesis, however, develops more slowly and is not restored within the observational period of 12 h. The experiment also shows that protein synthesis is resistant to irradiation of any cellular area at the dose used.

### Evidence for Direct Physical Bonding between the Collagen Fibres and Apatite Crystals in Bone

THE exact relationship between the mineral crystals and the collagen fibres in bone has not been determined. While the present consensus is that the collagen fibres initiate mineralization<sup>1,2</sup>, and that the initial crystallites have a specific spatial relationship to the collagen fibres<sup>3</sup>, evidence of the exact physical relationship between the fibres and crystals is lacking. This question pertains chiefly to the initial crystallization phase, because subsequent secondary mineralization is believed to occur on the basis of inter-crystalline bonding.

In a previous communication we reported the detection of electron paramagnetic resonance signals from whole human bone as well as extracted collagen and apatite<sup>4</sup>. Apatite, prepared by refluxing with ethylene diamine<sup>5</sup> and washing in distilled water, gave a complex signal consisting of a  $g$ -2 resonance and several lower field resonances. The  $g$ -2 resonance was ascribed to an  $F$  centre and the remaining resonances to various types of structured water. Because the whole bone signal consisted of a singlet at  $g$ -2.001 with a line width of 10 gauss, the relationship between the complex resonance of extracted apatite and that of apatite *in situ* was obscure. In an attempt to clarify this, evidence was obtained which indicated the existence of a direct physical bond between the apatite crystals of the initial mineralization phase and the collagen fibres.

Our initial hypothesis was that the complex apatite signal was largely artefactual, derived from absorption of water molecules in the washing process. Accordingly, we examined apatite after refluxing in ethylene diamine and vacuum drying but without washing in water. A weak  $g$ -2 singlet of 10 gauss width was observed (Fig. 1a). This signal was found to follow a simple Curie dependence between 114° K and 295° K. Subsequent washing of this material for 24 h in methanol or ethanol did not alter the signal. Similar washing in distilled water, however, resulted in the appearance of the previously reported complex apatite signal (Fig. 1b). The magnitude of the total resonance was directly proportional to the length of washing time up to 24 h; however, line width and shape remained constant. Substitution of mammalian Ringer solution for the washing medium resulted in a much distorted  $g$ -2 resonance with marked broadening (Fig. 1c).

Fig. 1. Electron paramagnetic resonances of extracted apatite and bone. Instrument gain is as noted and the arrow denotes  $g=2.000$ . The broad resonance, just to the low field side of  $g=2$  in the water washed whole bone spectrum, is probably the result of water absorption by the collagen fibres, not by apatite. In the water washed, powdered whole bone spectrum (lowermost in illustration), the three, equally spaced low field resonances are shown at a gain of 100 while the whole trace is at gain 6. The higher gain tracing is sweep synchronized with the whole trace.

These results indicated that apatite, prepared by removal of the matrix collagen fibre, was capable of taking up a variety of inorganic ions from solution. The method of preparation used dissolves all the organic matrix leaving the mineral crystals undisturbed. In this fashion free surfaces are created at the original sites of attachment between the crystals of the initial mineralization phase and the organic matrix. Because collagen constitutes more than 95 per cent of the organic fraction of bone, it is reasonable to expect that the majority of the corresponding binding sites are located on the collagen fibres. The intercrystalline bonds of the secondary phase of mineralization are assumed to be unbroken. It therefore appeared most likely that the ions removed from solution by apatite prepared in this fashion were bonding to sites of previous attachment to the collagen fibres. If this attachment was a direct physical bond, then whole bone subjected to prolonged washing in distilled water should not demonstrate the complex signal. Powdered whole bone (in which a significant number of free surfaces are produced by disruption of the intercrystal bonds of the secondary calcification phases), however, should demonstrate the complex signal. This was found to be the case; whole bone washed for 2 weeks in distilled water displayed an unchanged  $g=2$  resonance (Fig. 1d) while powdered whole bone similarly washed for 24 h revealed a complex signal very similar to that of apatite (Fig. 1e). The broad low field resonance in Fig. 1d is probably a result of absorption of water directly on to collagen fibres<sup>1</sup>.

We conclude, therefore, that the experiments described can be interpreted as supporting the thesis that a direct

physical bond exists between the initial apatite crystallites and the collagen fibres. The constancy of the  $g=2$  singlet from apatite under all experimental conditions would seem to indicate its presence in apatite *in situ* as well. In this case, it would contribute to the  $g=2$  resonance displayed by whole bone.

### Thermo-voltaic Radiation Dosimetry

THE most familiar process of solid state radiation dosimetry makes use of trapping processes in phosphorescent materials by monitoring thermoluminescent glow curves as a function of dosage received<sup>1</sup>. In previous papers<sup>2-4</sup> it has been shown that this process can be advantageously modified—at least in principle—in a number of ways. Its sensitivity, for example, can be increased by the application of high electric fields which accelerate thermally released electrons and thereby lead to impact ionization. Alternatively, it is possible to use “current-glow” or photo-stimulated currents<sup>3,4</sup> for dosimetric purposes. Because of the absence of light measurements, this leads to a considerable simplification of technique.

It has now been found that thermo-electric properties can be used for dosimetric purposes in a similar way. The principle is simple, though in practice a number of complications are observed. One would expect the incoming radiation to charge electron traps in proportion to the dosage received. Subsequent heating of the specimen in the presence of a thermal gradient should then yield a temporary thermopower which is lower than that associated with unirradiated specimens because of the release of free carriers from the traps. Once these carriers have recombined (whether thermally or radiatively), the original value should be restored.

In the exploratory work reported here, specimens of zinc sulphide in the form of a single crystal clamped between metal electrodes have been irradiated with ultra-violet light. One electrode is rapidly heated to produce a temperature gradient across the sample. In due course the temperature of the second electrode likewise increases, as a result of heat conduction through the crystal. Under final steady state conditions, the temperature difference is again small. The average temperature gradient thus passes through a maximum with time, and so does the corresponding thermo-voltage. Fig. 1 shows a set of results for three different dosages of ultra-violet. Irradiation by X-rays gives quite similar results. After each run, the specimen must be returned to its equilibrium condition. This is done by maintaining it at 400° C for 1–2 h. This procedure ensures repeatable results.

The process is essentially thermo-electric in character, but the conditions are complicated by at least two (probably related) factors: space charge regions arise

from local variations in the population of the filled trap and from the contact parameters. The last factor enters because opposite faces are not equivalent. The observed reversal of polarity is believed to be connected with these factors although the detailed mechanism is not yet fully understood.

As a dosimetric method, the procedures described here differ from those now in use inasmuch as the departures from zero dosage curves are most readily observed when the dosages are small. Saturation usually sets in at high dosages. It is not possible to compare the sensitivity of this method with that of other methods directly. Using zinc sulphide and photo-stimulated current dosimetry in the low temperature range ( $-100^{\circ}\text{C}$  to  $0^{\circ}\text{C}$ ), it has been shown that dosages down to  $0.01\text{ }\mu\text{W sec/cm}^2$  can be measured<sup>2</sup>. Above room temperature, the sensitivity of this process is extremely low, whereas the present procedures lead to still higher sensitivities of the order of  $1\text{ }\mu\text{W sec/cm}^2$ . Because it is only the range above room temperature which is of interest for practical purposes, this comparison favours the thermo-electric method. There are indications that its sensitivity at low temperature is comparable with that of photo-stimulated current dosimetry.

Fig. 1. Thermovoltage response versus hot electrode temperature as a function of ultra-violet dose. Zinc sulphide single crystal, undoped, containing a few p.p.m. of calcium, copper and magnesium. Electrodes on (0001) planes.

The absolute sensitivities recorded refer to specimens and heating programmes which have not been systematically optimized in any way. It is reasonable to expect improvements in sensitivity from appropriate adjustments of the available specimen parameters (including doping) and experimental procedures. Observations similar to those recorded here have been made on cadmium fluoride, lithium fluoride, strontium fluoride, calcium fluoride and beryllium fluoride. In zinc sulphide itself, the trap depth is insufficient to be capable of

storage at room temperature over periods longer than a few hours.

## GENETICS

### Evidence of Mutation within the Rhesus Blood Group System

As a result of studying the blood groups of many mother and child pairs for medico-legal purposes at the State Institute of Blood Group Serology, Stockholm, several rare Rh phenotypes have been detected<sup>1</sup>. Subsequent family studies have shown their inheritance to be of a straightforward Mendelian type.

Recently another case was encountered in which a child was found to have a previously undescribed phenotype which could be explained by postulating that a mutation has taken place in the mother's reproductive cells. In Fig. 1, it can be seen that the mother, II-1, having an Rh phenotype of ccDEe, was presumed to be of *DcE/dce* genotype as her parents were of phenotypes ccDEE and ccddee. The three children were all of phenotype CcDEe, and were of the genotype *DcE/DcE* by virtue of negative reactions with anti-ce(f) sera. Full grouping of the members available for testing failed to demonstrate whether the same man fathered all three children (Fig. 1). The two putative fathers of the child III-3 had phenotypes of CCDee and CcDee and neither were excluded from paternity. It was established that the mother has passed on the same *DcE* gene complex to each child, as she possesses only one. The *DcE* gene complex is normally expressed in III-1 and III-2 but is much weaker in III-3. Since the *DcE* gene complex is most probably combined with a *DCe* gene complex, it is not possible to show whether the D antigen is suppressed, but the c and E antigens in III-3 were never demonstrable with saline antisera and showed marked weakness with incomplete antisera after ficin-treatment. In order to confirm the presence of c and E antigens in child III-3, the cells were shown to absorb and yield on elution anti-c and anti-E.

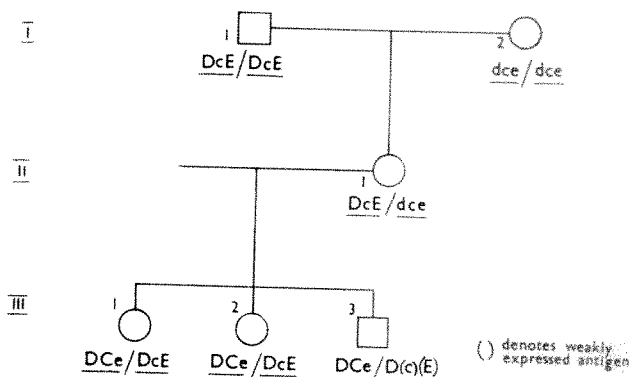

Fig. 1. Family study.

The serological results obtained in this family indicate that the *DcE* gene complex of the mother, II—1, is normally expressed as judged by reactions with anti-D and anti-E sera and that she has passed it on to her two older children, III—1 and III—2, as judged by reactions with both anti-c and anti-E sera. This same *DcE* gene complex has been modified in its expression on the third child's (III—3) red cells. All the other antigens, C, D and e, in child III—3 were quite normally expressed so that this case is not similar to those described by Levine *et al.*<sup>2</sup> and Giles and Bevan<sup>3</sup>, where all Rh antigens present in an individual were suppressed.

One can postulate that a gene mutation has occurred, and that the mother's *DcE* gene would be permanently expressed in the weak form.

Boettcher<sup>4</sup> devised a scheme which envisaged a series of biosynthetic pathways with a sequence of Rh genes acting on precursor substance. Each Rh gene is thought to control the specificity of a single enzyme. It is known<sup>5</sup> that mutations can affect enzyme activity completely or partially. If a mutation occurred along the genetic pathway between the D and C loci which resulted in partial reduction in enzyme activity for C (or c) and E genes, a gene complex of the type described above *D(c)(E)* might result. It must be stressed that it is not possible, in this study, to determine whether the D antigen was also affected by mutation, but if it were one would suggest that the mutation occurred earlier in the pathway before the D locus.

### Immunochemical Detection of Antigens in Self-incompatibility Genotypes of Cabbage

RECENT advances in immunochemistry permit the characterization of tissue specific antigens, and thus provide highly sensitive techniques for the study of gene action<sup>1</sup>. Of the new techniques available, immunodiffusion offers the following advantages over other serological tests: (a) multiple antigens from particular tissues can be resolved so that the antigens characteristic of different genotypes can be assessed; (b) only a small amount of plant tissue is needed to provide the test antigen; and (c) immunodiffusion tests are simple and easy to set up. This communication deals with the use of immunodiffusion to detect antigenic differentiation in plant tissues, specifically in relation to the control of self-incompatibility by multiple alleles of an "S" locus in plants<sup>2-6</sup>.

From each of four different inbred homozygous genotypes of *Brassica oleracea*, variety 'Capitata', anthers and parts of the pistil, including the upper third of the ovary, the style and the stigma, were extracted in physiological saline. Inbred plants A and C represented two self-incompatible genotypes, while inbred plants D and E represented two self-compatible genotypes. Except for expression of incompatibility, inbred C and inbred D are phenotypically indistinguishable. Inbred D represents a presumed self-compatible mutant arising from inbred C after the latter had been selected for high intensity of self-incompatibility and inbred (by bud pollination) for more than ten generations.

From each inbred, 5 g of anthers and 5 g of pistils (fresh weight) were separately extracted with saline solution (0.8 per cent sodium chloride) in a mortar with a pestle, using sand which had been cleaned with acid. After centrifugation at 5,000g for 15 min, the supernatant was removed and the pulp was again extracted for two additional cycles. The total supernatant collected was adjusted to 45 ml. A total of 15 ml. of a specific extract was injected into each of twenty-four rabbits. The injections were given twice a week during 4 weeks. Every fourth injection was given subcutaneously and the others were given intravenously. One injection was given with complete Freund's adjuvant at the ratio of 1:1. Six rabbits of each incompatibility genotype were used, three for anther and three for pistil extracts.

Two weeks after the last injection, the blood was collected and the sera were obtained by allowing separation from whole blood and clarification by centrifugation at 1,000g. Merthiolate was added as a preservative to give a final concentration of 1:10,000 and the sera were frozen and stored at -10° C. Pre-immunization sera collected from each of the twenty-four rabbits gave negative results with both anther and pistil extracts. Preliminary double diffusion tests with individual antisera led to the selection of the most concentrated serum against anther and pistil antigens of each genotype. Double diffusion at 5° C or at room temperatures and immuno-electrophoretic

Fig. 1. Intact stigmas reacted in agar double diffusion with anti-pistil antiserum C (centre well). Stigma genotypes, upper left and clockwise: C, D, C x D, C, E, A. Unique bands are resolved opposite C and C x D.

Fig. 2. Excised tissues of C pistil reacted in agar double diffusion with anti-pistil antiserum C (centre well). Left to right: stigma and ovary at the top, and stigma and style at the bottom. Tissue specific antigens are evident opposite the two individual stigmas and the ovary segment.

Fig. 3. Resolution, by reaction against anti-*C* serum, of freely diffusible antigens from six single stigmas from a sequence of developing flowers on a flowering raceme of inbred *C*. The age sequence from left to right is: 0, -1, -2, -3, -4, and -5, where 0 is anthesis and -5 is approximately 5 days before anthesis. 0, -1, -2 and -3 are self-incompatible and exhibit freely diffusible antigens while -4 and -5 are self-compatible and lack these antigens.

tests<sup>7</sup> failed to show consistent and unequivocal differences between anther homogenates obtained from the four genotypes and used as test antigens against homologous and heterologous sera. Anther homogenates were strongly antigenic in rabbits and a minimum number of seven precipitation bands were resolved in each genotype.

Excised mature anthers, used directly as test antigens, gave precipitation bands with anti-anther sera. One millimetre sections from anthers of different ages (*F*, *B*<sub>1</sub>, *B*<sub>2</sub>... *B*<sub>14</sub>) were excised and implanted as test antigens in agar double diffusion plates. (*F* refers to anthers from an open flower, while *B*<sub>1</sub> to *B*<sub>14</sub> refers to anthers from the first to the fourteenth consecutive bud above the youngest open flower on a raceme. Thus, *B*<sub>1</sub> refers to the oldest and *B*<sub>14</sub> to the youngest bud observed.) Distinct antigenic patterns were distinguishable for: (a) mature yellow anthers *F*, *B*<sub>1</sub> and *B*<sub>2</sub>; (b) yellow-green anthers of intermediate maturity (*B*<sub>3</sub> to *B*<sub>8</sub>); and (c) green immature anthers (*B*<sub>9</sub> to *B*<sub>14</sub>). Homogenates of samples from these three age categories of developing anthers also gave distinct antigenic patterns, and indicated that changes in soluble antigens accompany the development and differentiation of microspores. Acetocarmine squashes of individual anthers from each of the tested buds indicated that all the buds were in post-meiotic stages.

Reaction of pistil homogenates against anti-pistil sera gave fewer precipitation bands than did reaction of anther homogenates against anti-anther sera, and differences were observed among the pistil homogenates of the different incompatibility genotypes. Certain of these antigens diffused freely from unmutated stigmatic surfaces. As shown in Fig. 1, anti-pistil antiserum against inbred *C* (anti-*C*) indicated the presence of unique antigenic components in inbred *C* stigmas. Stigmas from none of six other incompatibility genotypes (including inbred *D*) gave the same number of bands as *C* stigmas when tested against anti-*C*. Precipitation bands became visible less than 24 h after reactants were placed on agar plates. Bands unique to the *C* genotype were evident only when stigmatic tissues were used as the source of antigens. The ovary exhibited tissue specific antigens (Fig. 2), but these were also present in the ovaries of other genotypes tested.

Diffusion of antigens from the unmutated stigmas presumably occurred through the papillary cells of the stigmatic surface. When the cut surface of the style was sealed with paraffin there was no effect on the diffusion of antigens from the excised stigmas. The role of the freely diffusible anther and stigmatic antigens is not known, but tests with developing stigmas suggest that the antigens may indeed play a part in self-incompatibility. Such tests were carried out with immature as well as mature stigmas of the self-incompatible inbred *C*. Buds of genetically self-incompatible cabbage plants exhibit self-compatibility

when pollinated in the intermediate and immature stages; at these stages they lack one or more of the unique and freely diffusible antigens present in stigmas of the self-incompatible buds and flowers (Fig. 3). Thus in a developmental sequence the appearance of self-incompatibility is correlated with the appearance of particular antigens.

The chemical nature of these stigmatic and anther antigens is not known, but some observations have been made. When the stigmatic homogenates are incubated at 60° C for 20 min and then used as test antigens, antigenic components are no longer detected by double diffusion. The stigmatic antigens migrate in an electric field as indicated by immuno-electrophoresis and are precipitated from solution by ammonium sulphate.

## CYTOLOGY

### Histones in Prophase and their Possible Role in Nuclear Membrane Breakdown

THERE is much interest in the histones in the context of the hypothesis that their biological function is to exert specific genetic repression in differentiated cells<sup>1-3</sup>. There is, however, evidence which does not support this hypothesis<sup>4,5</sup> but which suggests that the histones could have a structural role in the organization of chromatin<sup>6</sup>.

There have recently been several reports that these basic polymers also have considerable activity in a second area of cell function; they affect a number of properties associated with cell membrane systems, including both the surface membrane<sup>7-8</sup> and the mitochondrial membrane<sup>9</sup>. In some of these investigations the histones are active at concentrations so low that it is difficult to avoid the implication that this activity has some physiological significance. For example, uptake of albumin into S180 cells in tissue culture, a process presumably dependent on activity of the surface membrane, is stimulated by the arginine-rich histone fraction at concentrations as low as 10<sup>-8</sup> molar (0.3 µg/ml.)<sup>7</sup>, and the surface membrane of these cells shows evidence of functional damage (as shown by abnormal dye and protein permeability) by this histone fraction at concentrations of 3 × 10<sup>-6</sup> molar (100 µg/ml.). The mechanism of these effects on membrane function is not yet understood and might be indeed quite complex; a simple process could be envisaged in which the adsorption of positively charged polymer molecules to the plasma membrane reduces the net negative charge of the cell surface<sup>8,9</sup>, and in which the resulting reduction in the electrostatic interactions would lead to an increased deformability similar to that resulting from charge reduction by neuraminidase treatment<sup>10</sup>. Such a process would form a basis for the stimulation by basic polyamino-acids of phagocytosis<sup>6</sup>, which involves an infolding of the membrane to form vesicles; and also for the stimulation of the uptake of macromolecules (nucleic acids<sup>11</sup>, albumin<sup>7</sup>, and inulin (work by Amundsen and Ryser, in preparation)) assuming that this uptake occurs by a process of pino- or micropino-cytosis. Higher levels of polymer adsorption lead to impaired exclusion of dye and protein molecules in S180 cells<sup>7</sup>, probably by causing structural changes in the surface membrane similar to those induced in the erythrocyte membrane by low concentrations (2 µg/ml.) of polylysine<sup>8</sup>, where it can be observed directly that the

homogeneous fine structure of the membrane is converted by the basic polymer to a much coarser texture with marked discontinuities.

One aspect of the possible significance of these actions of histones and basic polymers on cell membrane systems concerns the possibility that such an action could be involved in the breakdown of the nuclear membrane at prophase. This possibility follows from evidence which suggests that there is a release at prophase of some of the nuclear histones from their association with DNA. This evidence includes the following. (1) The conclusion, from autoradiographic analyses, that chromosomal proteins in hamster fibroblasts and root meristem cells of *Vicia faba* are not conserved during mitosis like the DNA, but become completely dispersed during relatively few divisions<sup>12,13</sup>. In *Amoeba proteus* a large proportion of the nuclear protein synthesized in interphase is dispersed throughout the cytoplasm at the subsequent mitosis<sup>12</sup>; a similar process has been reported in epithelial cells of rats<sup>14</sup>. (2) In the nuclei of tissues containing a high proportion of cells in interphase, the histone:DNA ratio has been shown to be  $\sim 2$  whereas in tissues with a high proportion of cells in mitosis it is close to 1 (ref. 15), approximating the value usually found for isolated chromatin<sup>16,17</sup>. This difference is suggested to represent a fraction of the total histone which is only loosely bound; the results would be compatible with the dispersion into the cytoplasm of a fraction of the total nuclear histone when the nucleus undergoes mitosis. Such a process was also put forward to explain the observation that in regenerating liver the ratio of one histone fraction (designated fraction 2) to DNA falls during a wave of mitoses<sup>18</sup>. (3) The observation that ribosomes from HeLa cells in metaphase are inactive in polypeptide synthesis relative to ribosomes from interphase cells, but that activity may be restored by very mild treatment with trypsin<sup>19</sup>; it was proposed that histones, released from the nucleus at the time of breakdown of the nuclear membrane, could be responsible for this inhibition of ribosome function. Ribosomes from non-synchronized chick fibroblasts can also be made inactive by addition *in vitro* of 1  $\mu\text{g}/\text{ml}$ . of calf thymus histone or salmon protamin (unpublished results of Amos).

These observations taken together seem to constitute strong evidence that a fraction of the histones of an interphase nucleus may be released from its association with DNA at prophase. This release could be concurrent with the changes in the configuration of the DNA as it condenses from its diffuse configuration in euchromatin to the dense configuration of prophase chromosomes, and be caused by the different structural (or functional) role of histone in these two states.

From this conclusion, together with the observations that histones may cause marked changes in the properties and the structure of cellular membranes, there follows the possibility that histones, thus released from the DNA, could be responsible for the structural changes in the nuclear membrane at prophase.

The quantity of histone in an interphase nucleus of a mammalian cell is approximately  $6 \times 10^{-6}$   $\mu\text{g}$  (approximately equivalent to the quantity<sup>20</sup> of DNA), so that if 10 per cent (for example) of the total histone were released at prophase within a spherical nucleus of diameter 10  $\mu$  (volume  $5 \times 10^{-10}$   $\text{cm}^3$ ), the concentration of free histone could reach 1,000  $\mu\text{g}/\text{ml}$ . If the nuclear membrane behaves similarly to the surface membrane in the sense of its reactivity with, and sensitivity to, basic polymers (it appears to carry a negative charge, like the surface membrane<sup>21</sup>), marked changes in its properties and structure would be predicted to follow the release of this quantity of histone, which is much above the critical level causing damage to the surface membrane<sup>7</sup>. The observations cited above suggest the release at prophase of a proportion of the total histone considerably greater than this figure of 10 per cent used for illustration, but the activity of histones on intracellular membranes would

undoubtedly be modified by the presence of other cellular constituents. It would seem possible that the resulting histone concentration could be high enough to cause the dispersion of the nuclear membrane material which occurs at prophase; the structural changes in the perinuclear zone, which have been shown to coincide with the breakdown of the nuclear envelope<sup>22</sup>, could have the same origin. A number of polybasic compounds of low molecular weight induce "blebbing" and dissolution of the nuclear membrane<sup>23</sup>. In view of the observations that the lysine-rich histones are most active in condensing chromatin<sup>24</sup>, whereas the arginine-rich histones show greater membrane activity<sup>7,9</sup>, the possibility could also be considered that there is a predominance of the arginine-rich fraction in the histone released at prophase.

On the basis of such a model, it could be further speculated that the marked changes in cytoplasmic structure accompanying mitosis could also be associated with the diffusion of histones from the nucleus. The possibility that these changes are caused by the release of (undefined) substances from the chromosomes in the early stages of mitosis has already been proposed and discussed in some detail<sup>25</sup>; other results led to the conclusion that the changes in the nuclear membrane in mitosis are generated within the nucleus itself rather than in the cytoplasm<sup>26</sup>. It was also suggested that the increased movements of the surface membrane during mitosis are caused by an agent released from the chromosomes<sup>27</sup>. It is clear that there are several aspects of the model discussed here which are susceptible to experimental test.

### Deposition of Sporopollenin on Lamellae of Unit Membrane Dimensions

THERE are several reports of a lamellar inner part of the exine of pollen grains<sup>1-8</sup>. The number of species examined is small, but the sampling of plant families is wide enough to conclude that the deposition of sporopollenin in some kind of lamellar form is probably characteristic for at least the inner unornamented part of the exine of pollen grains.

In microspores of *Anthurium* sp., fixed in formalin<sup>9</sup> and stained with uranyl acetate and lead citrate<sup>10</sup>, we have direct evidence for the formation of some of the exine on lamellae of unit membrane dimensions. Sporopollenin accumulates on such membranes, often asymmetrically, to form the buttressing lamellae of the germinal apertures (Fig. 1). These buttressing lamellae grow to 0.3–0.4  $\mu$  in cross-sectional height, but they retain the line of low density characteristic of the unit membrane until near pollen maturity. In mature pollen only a staining discontinuity at the relative position of the uppermost line of low density around the apertures remains as an indication of the mode of origin (Fig. 2).

Fig. 1. Section of one side of a germinal aperture region in a microspore of *Anthurium*. The accumulation of sporopollenin on some of the unit membrane-like lamellae is asymmetric (arrow). Lines similar to the characteristic region of low density in the above lamellae are traceable (double-headed arrow) in all of the buttressing parts of the exine around the germinal aperture (P) including the one that is outermost. ( $\times$  c. 18,750.)

Fig. 2. Medial section of one side of a germinal aperture in a mature pollen grain of *Anthurium*. A staining discontinuity (arrow) can be traced in the outer part of the exine beside the pore (P). Strands of cytoplasm in the intine (I) are bounded by plasma membrane. ( $\times$  c. 15,000.)

Fig. 3. Section from an immature *Scapania nemorosa* spore wall. About five unit membrane-like lamellae (arrow) form the exine. The piles of dense material that constitute the ornamentation over the lamellae may also form on membranes but the amount of sporopollenin already present obscures that information. At spore maturity the membranous origin of all parts of the wall is obscured. ( $\times$  c. 50,250.)

In the spores of the liverwort *Scapania nemorosa* most of the spore wall has a laminar or unit membrane origin (Fig. 3). The wall of immature spores of *Scapania* is composed of a layer of low density overlain by acetolysis-resistant material (sporopollenin). The resistant components consist of about five lamellae having some characteristics of unit membranes surmounted by stacks of disks bounded by a membrane (Fig. 3). The piles of disks are irregularly shaped and spaced and appear similar to the ornamentations on spores of mosses reported by von Wettstein<sup>11</sup> and McClymont and Larson<sup>12</sup>. Working with *Geothallus*, Doyle<sup>13</sup> determined that two of the four wall layers of the spores gave reactions which indicated the presence of waxy compounds on a carbohydrate framework. The inner layer of the above two was composed of a series of lamellae and both layers gave histochemical reactions indicative of sporopollenin.

Heslop-Harrison<sup>6,7</sup> and Larson and Lewis<sup>4</sup> have presented micrographs showing endoplasmic reticulum oriented parallel to the plasma membrane in regions of presumptive germinal apertures. These writers have strongly suggested that the position of elements of the endoplasmic reticulum influences the deposition of the exine. We do not know the source of the membranes, but lines of low density are about 40 Å in cross-sectional height and highly regular as would be expected of a paracrystalline molecular system such as the unit membrane. The minimal dimensions for the two dense outer areas measured 60 or 100–120 Å. The 60 Å dense bands may be a single strand of sporopollenin similar to Rowley's<sup>14</sup> description of stranded sporopollenin in the exine of *Poa annua* microspores or to the description of Afzelius<sup>1</sup> of aligned granules. The dense parts that were measured at 100–120 Å in thickness may consist of two layers of sporopollenin strands.

Afzelius<sup>15-17</sup> found lines of unit membrane dimensions in mature exines of *Acmopyle* and *Sequoia* pollen and of *Lycopodium* spores. In *Nuphar*, Rowley (unpublished data) observed low density lines of 35–40 Å width aligned both parallel and perpendicular to the ornamented surface of the exine. In *Nuphar* the low density lines extend through the entire length of 0.5  $\mu$  spinules.

The presence of unit membranes around isolated agglomerations of sporopollenin (Ubisch bodies), which are

found at considerable distances from microspores, is further evidence of a universal mode of sporopollenin deposition on unit membranes. While working with Professor G. Erdtman on pollen of *Populus tremula*, we observed membrane bound Ubisch bodies located between tapetal cells.

## MICROBIOLOGY

### Sensitivity of *Trypanosoma equiperdum* to the Action of Tumour-inhibitory Antibiotics *in vivo*

THE marked sensitivity *in vitro*<sup>1</sup> of various metabolic pathways in *T. equiperdum* to actinomycin D, mitomycin C, porfiromycin, phleomycin, and pactamycin indicated that these tumour-inhibitory antibiotics may be trypanocidal *in vivo*. Our results show this to be so with all except pactamycin, and also that phleomycin and porfiromycin in particular cured a high percentage of infected mice at certain dosages.

Female *Ha/ICR* albino mice, 19–22 g, were inoculated intraperitoneally with about  $1 \times 10^6$  viable trypanosomes (by haemocytometer count) obtained from the blood of infected mice and suspended in isotonic saline containing 1 per cent glucose. The strain of *T. equiperdum* used in these experiments was obtained several years ago from Dr. David Weinman, Yale University School of Medicine, and the parasites have been propagated by mouse-to-mouse passage since that time. Untreated infected mice invariably died 52–70 h after inoculation. The efficacies of the maximal tolerated quantities of each antibiotic at repeated and single doses were compared. The time when each group of ten mice was first injected with an antibiotic is given in Table 1.

Using separate groups of similarly infected mice, blood collected periodically by orbital puncture was examined to determine changes in parasitaemia during the course of three consecutive single daily intraperitoneal injections of the antibiotics, treatment starting 24 h after inoculation. The haemocytometric technique for counting these blood forms is described in detail elsewhere<sup>2</sup>.

The trypanocidal property of phleomycin (8 mg/kg), porfiromycin (10 mg/kg), and mitomycin C (4 mg/kg) is

shown in Fig. 1. These antibiotics, when injected intraperitoneally into infected mice at 24, 48, and 72 h after inoculation, in each instance caused a significant reduction in parasitaemia within 6 h, which became most marked within 12 h. Thereafter, the surviving trypanosomal population began to increase, but at a rate slower than normal. Although the trypanocidal potency of phleomycin and porfiromycin apparently did not change with repeated injection, that of mitomycin C seemed to become progressively weaker under these conditions. Pactamycin (4 mg/kg) and actinomycin D (0.1 mg/kg) were not trypanocidal and altered the course of parasitaemia only slightly when injected intraperitoneally under the conditions already described. It has been reported<sup>3</sup> that a given dose of actinomycin D injected subcutaneously is more efficacious in tumour-bearing mice than when injected intraperitoneally; the effect of actinomycin D (0.1 mg/kg) given subcutaneously under the conditions already described was re-examined. It can be seen from Fig. 1 that daily doses of actinomycin D injected subcutaneously, although still not apparently trypanocidal, were capable of prolonging significantly the doubling time of blood-dwelling trypanosomal populations. Not shown in Fig. 1 but important in the subsequent adoption of optimal dosages were these findings: (1) the trypanocidal potency of phleomycin and porfiromycin injected intraperitoneally was much greater when the total maximally tolerated dose was divided into equal portions injected every 12 h than when larger portions were injected once daily or the entire amount at one time; (2) the trypanocidal potency of actinomycin D was revealed when the total maximally tolerated dose was injected subcutaneously at one time rather than in portions injected every 12 h or once daily.

The comparative efficacies of different antibiotic dosages in prolonging the life and curing mice infected with *T. equiperdum* are shown in Table 1. All regimens provided almost maximally tolerated total doses of each antibiotic, and it would appear that phleomycin was the most effective of those antibiotics tested in the treatment of this experimental trypanosomiasis. Its marked curative action when given intraperitoneally at intervals of 12 h starting shortly after the mice were inoculated with parasites still held when treatment under this regimen was delayed for 24 h. In advanced trypanosomiasis, when treatment was delayed for 48 h, phleomycin no longer effected a

Table 1. COMPARATIVE EFFICACIES OF DIFFERENT DOSAGE REGIMENS OF PHLEOMYCIN, PORFIROMYCIN, MITOMYCIN C, ACTINOMYCIN D, AND PACTAMYCIN IN THE TREATMENT OF MICE INFECTED WITH *Trypanosoma equiperdum*

"	—	10	1	79 ± 4	0

*Ha/ICR* female albino mice, 19–22 g, were inoculated intraperitoneally with about  $1 \times 10^6$  viable trypanosomes, and were randomized into groups of ten. Each group was treated with an antibiotic given by either of two regimens: (1) at a dose listed in the column indicated by (\*), injected intraperitoneally (unless otherwise indicated) six consecutive times every 12 h, starting at a time after inoculation of parasites listed in the column indicated by (†); (2) at a dose listed in the column indicated by (†), injected intraperitoneally (unless otherwise indicated) just one 1 h after inoculation of the parasites. Controls received comparable volumes of isotonic saline solutions given by identical regimens. Standard errors of the average survival times calculated for each treated group (in duplicate) appear in the column indicated by (§). Such calculations were not performed when 70 per cent or more of the treated mice were cured.

Fig. 1. *Ha/ICR* female albino mice, 19–22 g, were inoculated intraperitoneally with about  $1 \times 10^4$  viable trypanosomes, and were randomized into groups of ten. Each group treated with an antibiotic received intraperitoneal injections at 24, 48 and 72 h after inoculation of the parasites. Injections were by the intraperitoneal route unless otherwise indicated. The doses used were: phleomycin, 8 mg/kg; porfiromycin, 10 mg/kg; mitomycin C, 4 mg/kg; actinomycin D, 0.3 mg/kg; and pactamycin, 4 mg/kg.

cure, but it retained its ability to prolong markedly the lives of the hosts. The 12 h intraperitoneal dosage regimen was clearly superior to that using a single injection of the total maximum tolerated dose.

The mitosane antibiotics, mitomycin C and its methyl congener, porfiromycin, were qualitatively similar in their action against *T. equiperdum in vitro*<sup>1</sup>, and this was apparently also the case with regard to their effects on the course of parasitaemia *in vivo* (Fig. 1). While both mitosane antibiotics, at maximally tolerated doses, could markedly prolong the lives of mice infected with *T. equiperdum*, porfiromycin cured a much higher proportion of infected animals. The finding in this instance that porfiromycin has a more favourable therapeutic index than has mitomycin C is similar to that reported by others<sup>4</sup>. Like phleomycin, porfiromycin was more effective when given intraperitoneally at intervals of 12 h than when given by the intraperitoneal route in a single maximal tolerated dose. But, unlike phleomycin, porfiromycin lost most of its curative power when treatment was delayed for 24 h.

The results in Table 1 clearly indicate that a given dose of actinomycin D was more effective when injected subcutaneously than when injected intraperitoneally. Actinomycin D effected cures only when it was injected subcutaneously shortly after inoculation of the mice with parasites in a single maximally tolerated dose.

Despite its ability *in vitro* to interfere with several metabolic pathways of *T. equiperdum*, especially in the

area of carbohydrate metabolism<sup>1</sup>, pactamycin was almost inactive *in vivo* when given in a repeated or in a single dose shortly after inoculation of the mice with parasites. This discrepancy, as well as those already mentioned with regard to influence of the injection route on the efficacy of actinomycin D and the influence of chemical structure on the efficacy of the mitosane antibiotics, is probably related to pharmacological factors such as degree of serum binding and rate of inactivation by the liver.

It is of more than passing interest that phleomycin<sup>5</sup>, porfiromycin<sup>6</sup>, mitomycin C<sup>7</sup>, and actinomycin D<sup>8</sup>, which are more or less effective as curative agents in experimental trypanosomiasis caused by *T. equiperdum*, are derived from various species of *Streptomyces*. Thus, these antibiotics can be included in a growing family of trypanocidal substances, with disparate chemical structures, which are derived from the same genus<sup>9</sup>. Perhaps it is not too unrealistic to hope that further investigation will lead to the discovery of related trypanocidal antibiotics with therapeutic indices sufficiently favourable to be useful in veterinary or human medicine.

This investigation was supported by a grant from the National Cancer Institute, U.S. Public Health Service.

### A D Serotype of Satellite Virus specifically associated with a D Serotype of Tobacco Necrosis Virus

Kassanis and Nixon<sup>1</sup> and Kassanis<sup>2</sup> reported that the Rothamsted strain of tobacco necrosis virus (RTNV) contains two serologically unrelated viruses with different sized particles; one with smaller particles (17 mμ) called "satellite virus" caused no lesions on beans and multiplied detectably only when present in mixed infections with the large particle (27 mμ) TNV. Tobacco mosaic, lucerne mosaic, carnation ringspot, and tomato bushy stunt viruses failed to make the small particles multiply<sup>1</sup>. All strains of TNV, except strain D, were reported to induce multiplication of satellite although some strains apparently were more effective than others<sup>3</sup>. Several strains of TNV were classified into two serotypes, A and D<sup>3</sup>. Strains A, B, C, F and S which supported multiplication of satellite are in serotype A. Strain E, which was also reported to support multiplication feebly, and strain D, which did not, are in serotype D. Babos and Kassanis<sup>3</sup> concluded that the ability of these strains to induce the multiplication of satellite was not related to their antigenic composition. We have found, however, that the satellites associated with different serotypes of TNV are serologically distinct, as are the virus strains with which they are associated.

In designations of serotypes of our isolates of TNV, we have followed Babos and Kassanis<sup>3</sup> and based our classification on reactions with antisera specific for A and D viruses kindly supplied by Dr. Kassanis. Moreover, the relative serological relationship of different cultures of

satellite is based on a comparison of the reaction of RTNV satellite (*A* serotype) with its specific antiserum and the reaction of a satellite associated with *AC* 36 TNV (American Type Culture Collection) which is a *D* serotype.

RTNV was increased in tobacco (*Nicotiana tabacum* L., Turkish) and *AC* 36 in pumpkin (*Cucurbita pepo* L., small sugar). Virus and satellite were partially purified by methods similar to those described by Kassanis and Nixon<sup>1</sup> and were further purified and separated by centrifugation in sucrose density gradients<sup>5</sup>. Contents of the gradient tubes were fractionated and recorded with an Isco 'Mod. D' density gradient fractionator<sup>6</sup>. Both virus and satellite were well separated in the first density gradient centrifugation, so recentrifugation of the separated components in density gradients produced a discrete band that appeared as a single peak which absorbed ultra-violet when gradient tubes were analysed and recorded with the Isco fractionator.

Purified virus and satellite appeared to be homogeneous as indicated by electron microscopy, the formation of single discrete bands in density gradients, and specific serological reactions with their respective antisera.

The satellite associated with *AC* 36 was approximately 18.0 m $\mu$  in diameter (Fig. 1) and sedimented at about the same rate in density gradients as the RTNV satellite. Thus it is similar to the RTNV satellite in both size and density.

Fig. 1. Electron photomicrographs of (A) *AC* 36 TNV, and (B) *AC* 36 TNV satellite. Particles were negatively stained with phosphotungstic acid. ( $\times 225,000$ .)

Before use as injection antigens for production of antisera or as test antigens, virus and satellite were centrifuged in sucrose density gradients from one to four times depending on the degree of purity desired. Antisera for RTNV, RTNV-satellite, *AC* 36 virus and *AC* 36-satellite were prepared by a series of interveinal, intramuscular or subcutaneous injections with the respective purified antigens. The antigens were emulsified with Freund's incomplete adjuvant for the latter two types of injections. All serological comparisons were made by immunodiffusion precipitation tests in agar gel using methods described previously<sup>4</sup>. Dilution end point titres of the antisera expressed as reciprocals of dilutions to homologous and

heterologous antigens, respectively, were: RTNV satellite 8192 and 1024; RTNV virus, 512 and 64; *AC* 36 satellite, 8192 and 256; and *AC* 36 virus, 8192 and 256. The RTNV satellite antiserum received from Dr. Kassanis was reported to have a titre of 80 to homologous antigen; it reacted positively with *AC* 36 satellite, but its titre to this antigen was not determined.

Results from serological tests in which purified virus or satellite antigens were placed opposite their respective homologous antisera in a four-member pattern in agar gel (not illustrated) showed that the lines of precipitation formed by the respective homologous reactants crossed without apparent deflexion. These results indicate that virus and satellite are not serologically related or are, at most, only very distantly related; they support the conclusions of Kassanis and Nixon<sup>1</sup>.

Fig. 2. Immunodiffusion precipitin patterns in agar gel produced by reaction of antisera for RTNV satellite, *AC* 36 satellite, and *AC* 36 TNV, with virus and satellite antigens. (1) *KS*-RTNV satellite antiserum from Kassanis; (2) *ACS*-*AC* 36 satellite antiserum; (3) *RS*-our RTNV satellite antiserum; and (4) *ACV*-*AC* 36 virus antiserum. Antisera were placed in the central wells and antigens in outer wells, designated as follows: *HT*, healthy tobacco; *ACS*, *AC* 36 satellite; *ACV*, *AC* 36 virus; *RS*, RTNV satellite; *RV*, RTNV; *HSS*, healthy small sugar pumpkin; and *HB*, healthy bean.

The reaction pattern produced when RTNV satellite antiserum received from Kassanis (*KS*, Fig. 2-1) was tested with RTNV satellite and *AC* 36 satellite antigens was identical with the pattern formed when our antiserum to RTNV satellite was tested with the same antigens (Fig. 2-3). The homologous lines of precipitation joined the lines formed by reaction with *AC* 36 satellite, but a distinct spur of precipitate was formed as an extension of the RTNV satellite line.

When the two antigens were similarly tested with antiserum for *AC* 36 satellite (Fig. 2-2) the lines of precipitate again joined, but the spur in this case was an extension of the *AC* 36 satellite line. This shows that the two satellite antigens are serologically related but mutually distinct serologically. The two *A* and *D* serotype viruses, RTNV and *AC* 36, have a similar serological relationship as demonstrated in Fig. 2-4. The line of precipitate formed by *AC* 36 and its specific antiserum joined the line formed by reaction with RTNV, but there was a distinct spur

which is an extension of the homologous line of precipitate. Reaction of the two viruses with RTNV antiserum (not illustrated) produced a similar pattern but with the spur forming as an extension of the RTNV line of precipitation. Thus the serological relationship of the two viruses is comparable with that of the two satellites in that they also are serologically related, but distinct.

Mixed inoculation of RTNV satellite with AC 36 virus resulted in production of only AC 36 satellite in the same amount and ratio to virus as when highly purified ( $5\times$  density gradient) AC 36 virus was inoculated alone.

This latter result indicates a need to determine with more certainty whether it is possible to free TNV cultures of satellite if they originally contained it. It should be pointed out here that certain TNV strains, for example Kassanis' TNVD, produce very little and usually no demonstrable satellite and this strain was reported by Babos and Kassanis<sup>3</sup> as not supporting production of satellite. Kassanis and Nixon<sup>1</sup> were unable to obtain TNVa or TNVb (serotype A) entirely free of satellite and suggested that a reasonable explanation for this failure was accidental contamination. Reichmann<sup>7</sup> stated that he had obtained satellite-free TNV as indicated by failure of satellite antiserum to react in agar gel double diffusion tests with extracts from TNV-infected plants. In contrast with Reichmann's claims, however, we have failed in many attempts to obtain a culture of RTNV that would not produce satellite when subcultured. For example, a culture of RTNV derived by successive isolation from five single isolated local lesions was increased and then purified by five successive isolations from sucrose density gradients. This culture was increased and shown by density gradient analysis and serological tests to contain satellite despite extreme precautions taken to prevent accidental contamination. This involved use of steam sterilized soil, pots, and saucers, which is a routine practice in our glasshouses, and isolation, in this instance, in a glasshouse free from other cultures of TNV. Furthermore, uninoculated controls were not infected with TNV.

If the interpretation by Kassanis and Nixon<sup>1</sup> and Kassanis<sup>2</sup> concerning the nature of satellite is correct, it should be possible to obtain cultures that do not produce satellite, but, with the exception of Reichmann<sup>7</sup>, no one has claimed to have done this. Kassanis and Nixon<sup>1</sup> suggested that TNV may not be able to function without satellite as an alternative explanation for their failure to obtain satellite-free cultures of TNV. We suggest that another, and possibly more likely, explanation is that the small satellite particles are always formed in some unknown fashion when the large particles are reproduced.

Our finding that the virus and satellite association is specifically related to serotypes of both entities plus the failures that we have experienced in eliminating satellite from TNV cultures indicates a need for further investigation concerning the nature and origin of satellites associated with TNV.

## HAEMATOLOGY

### Erythrocyte Acid Phosphomonoesterase Activity in Newly Born Chinese deficient in Glucose-6-phosphate Dehydrogenase

In connexion with our investigations of the aetiological factors responsible for the high incidence of neonatal jaundice among Chinese infants in Taiwan, we have measured the concentrations of erythrocyte acid phosphomonoesterase in normal and Chinese newborn infants and those deficient in glucose-6-phosphate dehydrogenase (G-6-PD). Our experiments on the acid phosphomonoesterase enzyme were prompted by the studies of Oski *et al.*<sup>1</sup> and Choremis *et al.*<sup>2</sup>. In the results reported by Oski *et al.*<sup>1</sup> there was a difference between the acid phosphomonoesterase activities in erythrocytes of Negroes deficient in G-6-PD and those of Caucasians deficient in the enzyme. Specifically, Oski *et al.*<sup>1</sup> found that the acid phosphomonoesterase activities of Caucasians deficient in G-6-PD were reduced whereas those of Negroes deficient in G-6-PD were equal to those of normal Negroes and Caucasians. Oski *et al.*<sup>1</sup> were interested in comparing the biochemical profiles of Caucasians and Negroes deficient in G-6-PD because of the apparent difference in the nature of that defect in the two groups. For example, it has been suggested<sup>1</sup> that Negroes deficient in G-6-PD show a less acute haemolysis than that experienced by deficient Caucasians<sup>3</sup> after eating broad beans (*Vicia faba*). It has also been reported that not all individuals from the same ethnic group who are deficient in G-6-PD are equally susceptible to favism<sup>4-6</sup> nor do they experience equal degrees of severity of neonatal jaundice<sup>6</sup>. In these circumstances it is reasonable to seek differences among other enzyme systems the normal operations of which influence the levels of the intermediary metabolites involved as precursors or products of G-6-PD action. Acid phosphomonoesterase is an enzyme of this type.

In the present experiments, fourteen newly born male Chinese deficient in G-6-PD and 23 normal newborn Chinese, twelve male and eleven female, were tested for their erythrocyte G-6-PD and acid phosphomonoesterase activities. All were chosen from infants born at the National Taiwan University Hospital, Taipei City; the infants deficient in G-6-PD were located by our modification of the Motulsky and Campbell dye decolorization test<sup>6</sup>. The normal infants were taken at random, except that those with haemolytic disorders due to ABO or Rh incompatibilities were excluded. Quantitative estimations of G-6-PD were carried out by the method of Zinkham *et al.*<sup>4</sup> and the method of King *et al.*<sup>7</sup> was used to determine the acid phosphomonoesterase activity. Both activities were expressed as units per 100 ml. of packed erythrocytes.

The results of these determinations are summarized in Table 1. It is apparent that, among the present Chinese subjects, there was no difference between the acid phosphomonoesterase activities of the normal infants and those of infants with G-6-PD deficiency. These results, unlike those reported for Caucasians of mixed origins by Oski *et al.*<sup>1</sup> and for Greeks by Choremis *et al.*<sup>2</sup>, suggest that

Table 1. ACTIVITIES OF ERYTHROCYTE ACID PHOSPHOMONOESTERASE AND G-6-PD ENZYMES IN NEWBORN CHINESE INFANTS (units/100 ml. packed erythrocytes)

Type of infants	No.	G-6-PD activity			Acid phosphomonoesterase activity		
		Range	Mean	S.D.	Range	Mean	S.D.
Normal males	12	155-503	304	$\pm 108$	286-703	463	$\pm 101$
Normal females	11	223-318	275	$\pm 35$	266-624	408	$\pm 94$
Combined normals	23	155-503	290	$\pm 81$	266-703	437	$\pm 99$
G-6-PD deficient infants	14	0-50	14	$\pm 4$	345-647	488	$\pm 87$

there is no close association between deficiencies of erythrocyte G-6-PD and acid phosphomonoesterase enzymes in Chinese. Furthermore, deficiency of acid phosphomonoesterase activity seems unlikely to be involved as an aetiological factor of any importance in neonatal jaundice among Chinese.

### Erythrocyte Volume Distribution during Recovery from Bone Marrow Arrest

Bröcher and Stohlman<sup>1</sup>, Borsook *et al.*<sup>2</sup>, and Seno *et al.*<sup>3</sup> have shown that macrocytosis results from erythropoietic stimulation by phenylhydrazine anaemia, bleeding or administration of erythropoietin. The macrocytic reticulocytes which result from skipped terminal division were shown to have a shortened life span and to be replaced by red cells of more normal size. This communication reports that radiation produces a similar macrocytosis in mice. We found during the experiment that the volume of mouse red cells decreases as they age.

Thirty female mice of *RF* strain, 6 weeks of age, were used. Twenty mice received a dose of cobalt-60 gamma-rays at a rate of 5 rads/h for 13.3 days (total 1,600 rads). Ten control mice were treated in the same manner but were not irradiated. We have previously found that this dose causes bone marrow arrest, probably within the first few days of exposure, and that 1,600 rads at this dose rate is the approximate  $LD_{50}$  dose for our *RF* strain<sup>4</sup>.

Blood samples were taken from four or five irradiated mice and two control mice at intervals of 2-4 days during a recovery period of 4 months. The orbital bleeding technique described by Riley<sup>5</sup> was used, and a blood volume of approximately 250  $\mu$ l. was taken from each mouse at each bleeding. Individual mice were allowed 9-14 days between bleedings. The red cell volume distribution and concentration were measured with a modified Coulter counter using an aperture 30  $\mu$  in diameter and 225  $\mu$  long and a 400-channel pulse-height analyser to allow a more accurate and detailed estimate of size distribution. Reticulocyte counts were made from slides of blood smears stained with methyl blue and Wright's stain.

The experimental size distributions were fitted with an iterative least-squares computer code<sup>6</sup>. A skewed normal distribution<sup>7</sup> was used, although the fit obtained with a normal distribution was almost as good. In cases where two populations were present, the sum of two normal distributions was used because the extra two parameters required for skewed distributions sometimes made convergence difficult.

Fig. 1 shows red cell volume distribution results at 15 and 34 days after irradiation and also for a control animal. Before the appearance of the second population the volume distributions were similar in shape to the controls, but they had a smaller mean volume and area

that is, red cell count). The second population of large cells appeared between the ninth and thirteenth days after irradiation; on the fifteenth day the mean volume of these cells was maximal. Microscope examination of the dry films showed them to be reticulocytes, and reticulocyte counts made from the slides agreed with those from the volume distributions. The reticulocytes could not be distinguished in the slides a few days later.

Fig. 2 summarizes the results of the computer fits to all the experimental data. The quantities plotted are the area (that is, the red cell count), the mean cell volume, and the fractional standard deviation of the fitted functions, all normalized to the control values. In the cases where the sum of two normal distributions was used in the fit, we have also plotted the mean cell volume for each population. The normalized area, which is the red cell count relative to the controls, was about 85 per cent of normal at the end of the exposure to gamma-rays, dropping to 50 per cent 10 days later. It then climbed rapidly as the second population appeared and returned slowly to near

Fig. 1. Volume distribution of mouse red cells 15 and 34 days after irradiation compared with control; the area under the curve is proportional to red cell count.

Fig. 2. Variation with time of red cell volume distribution parameters derived by computer after the end of exposure to gamma-rays, normalized to control values. The curve labels have the following significance: area is red blood cell count; mean, is mean cell volume of the first population; mean<sub>2</sub>, is mean cell volume of the second population; mean is mean cell volume of the overall population; and SD/mean is the ratio of standard deviation of the overall population to the mean cell volume of the overall population.

normal. The mean cell volume was also slightly (2 per cent) below normal initially, and fell steadily for about 10 days to 7 to 8 per cent below normal, then rose rapidly to 30 per cent above normal as the reticulocytes entered the circulation. Thereafter, there was a slow decline to normal over a period of 60–70 days. The width of the distribution, as indicated by the fractional standard deviation, showed similar changes but with a greater rise (to 65 per cent above normal) as the reticulocytes appeared. The mean cell volume of the second population reached a maximum value of 60–70 per cent above normal on the fifteenth day and then declined to 20 per cent above normal at day 33. The mean cell volume of the erythrocytes (first population) declined to 9 per cent below normal by the thirteenth day after the end of exposure, then increased to about 9 per cent above normal, and then decreased and slowly approached normal. At this point (34 days), it was no longer possible to resolve the distributions into two populations.

Before the appearance of macrocytic reticulocytes, the circulating red cells constituted an ageing population, because the supply of young erythrocytes had been blocked by the radiation. The red cell count dropped as would be expected, but the mean cell volume also decreased. In addition the population became more homogeneous, as was shown by the decrease in the ratio of standard deviation to mean cell volume. These observations indicate that the red cell volume in mice decreases as the red cells age, and adds to the list of properties already known to be dependent on age, such as density and osmotic fragility<sup>8</sup>. This experiment also shows that recovery from bone marrow arrest induced by radiation involves the same kind of changes in red blood cells that are induced by anaemia and erythropoietin administration.

We thank N. J. Basmann and J. M. Hardin for technical assistance. This work was performed under the auspices of the U.S. Atomic Energy Commission.

## IMMUNOLOGY

### Serum Proteins in the Germ-free Mouse after Oral Challenge with *Candida albicans*

THE serum of many conventional and so-called germ-free animals contains bactericidal activity against certain Gram-negative bacteria<sup>1</sup>. This activity is effective against those bacteria commonly found in the intestinal tract or bacteria related to them. Even the feeding of heat-killed bacteria to germ-free chicks results in specific agglutinin<sup>2</sup>. Thus it appears that antigens from the lumen of the gut may become transported to sites of antibody synthesis. It is well established that gamma globulin and possibly other serum globulins are decreased in germ-free animals<sup>3–5</sup>. All immunoglobulins were markedly decreased in the germ-free mouse<sup>6</sup>.

*Candida albicans* frequently occurs in the normal microbial flora of the alimentary tract of many animal species, although it is apparently not present in the laboratory mouse. In man there are many individuals with antibodies against *C. albicans* in the absence of frank candidiasis. The question, however, remains whether these antibodies are produced in response to subclinical infection, or whether antigens of *C. albicans* are transported from the gut to the antibody producing sites. These topics, as well as others relating to *C. albicans*, were recently reviewed<sup>7</sup>.

The present communication gives the results of an investigation of changes occurring in some serum proteins in the germ-free mouse after association with *C. albicans*.

*Candida albicans* ATCC 10231 was maintained on Sabouraud dextrose agar slants. This strain had an  $LD_{50}$  for mice after intravenous injection of about  $10^6$  viable cells. Isolates of micro-organisms from tissue or other sources were tested for their ability to produce mycelia, blastospores, and chlamydospores by inoculation and growth on corn meal agar for identification of *C. albicans*.

Germ-free mice of the ND 4 strain were originally obtained from Manor Farms Inc., Staatsburg, N.Y.; they were reared as a colony in our laboratory. A crude diet was fed after autoclaving for 25 min at 125° C. Animals were housed in 'Plexiglas' isolators<sup>8</sup>, but the following modifications were made in the equipment and procedures. The germicidal liquid lock was replaced with an interlock sterilized with peracetic acid, and an autoclavable transfer container<sup>9</sup>. Our colonies of germ-free mice have been maintained for almost 3 years.

The pooled blood serum from fifteen to twenty animals in each group was analysed for serum proteins with an analytical electrophoresis apparatus. Preparation of inoculum and inoculation of animals were done as follows. An overnight culture of *C. albicans* was grown at 37° C in Sabouraud dextrose broth in a glass ampoule which was then sealed and transferred into an appropriate isolator using the usual precautions to avoid extraneous contamination of animals. The ampoule was opened and the culture mixed with food, each animal receiving about  $10^6$  viable cells. Cultures were usually administered once only. Gnotobiotic animals were examined periodically for their microbial association as described<sup>10</sup>, but no extraneous contamination was observed in the experiments described here.

Tissue sections were prepared for histology from the following organs: stomach, small intestine, caecum, large intestine, liver, kidneys, pancreas, spleen, lungs. After fixing in neutral buffered formalin, duplicate tissue sections were stained with haematoxylin-eosin (HE) and periodic acid-Schiff stain (PAS). As a test for the presence or imminence of infection we looked for hyphal forms in stool specimens. Finally, the stained histological sections from each animal were examined.

The concentrations of serum proteins in germ-free and conventional mice are shown in Table 1. It is clear that the concentrations of gamma-globulin and beta-globulin in germ-free animals were substantially lower than in conventional mice. Concentrations of total serum protein were similar in both groups.

After association of germ-free mice with *C. albicans* the level of gamma-globulin increased with age, but did not achieve the level in conventional mice (Table 1 and Table

Table 1. SERUM PROTEINS IN CONVENTIONAL AND GERM-FREE MICE, AND IN THE GERM-FREE MOUSE AFTER ASSOCIATION WITH *Candida albicans*

Serum protein	Protein recovered (percentage of total serum protein)		
	Germ-free mice	Conventional mice	Mice with <i>C. albicans</i>
Albumin	57.4	38.3	53.0
$\alpha_1$ -Globulin	10.4	8.0	9.0
$\alpha_2$ -Globulin	17.1	6.2	9.4
$\beta$ -Globulin	14.9	35.8	23.3
$\gamma$ -Globulin	<0.5	11.7	6.0
Total protein in serum (g/100 ml.)	6.2	6.3	4.7

2). Moreover, there appeared to be a decrease in alpha-2-globulin with age in these animals (Table 2), whereas albumin and beta-globulin increased. After sera from germ-free, conventional and gnotobiotic (*C. albicans*) animals were mixed with *C. albicans* cells (and the remaining soluble proteins determined), total serum protein was decreased (Table 3). The most notable change was a decrease in the alpha-2-globulin in the gnotobiotic group. Each group of animals was autopsied and examined for infection. No infections were evident in the organs and tissues examined despite the fact that large numbers of budding yeasts ( $10^4$ – $10^8$ /g wet weight) were seen throughout the lumen of the gut of the gnotobiotic group (*C. albicans*). Many yeast cells appeared to be in close association with the mucosa of the intestine, although penetration of the mucosa was not evident; few hyphae or mycelia were seen. *Candida* species could not be recovered from conventional animals not fed *C. albicans*.

Table 2. SERUM PROTEINS IN GERM-FREE MICE OF DIFFERENT AGES AFTER ASSOCIATION WITH *Candida albicans*

Age of animals (months)	Total serum protein recovered (g/100 ml.)	Proteins recovered (percentage of total protein)				
		Albumin	alpha-1	alpha-2	beta	gamma
1	5.2	29	4	60	7	<1.0
4-6	6.9	56	7	24	11	2
12	4.7	53	9	9	23	6

Table 3. SERUM PROTEINS IN GNOTOBIOTIC AND CONVENTIONAL MICE AFTER SERUM ABSORPTION WITH *Candida albicans* CELLS

Microbial status of animals*	Total serum protein (g/100 ml.)	Serum protein (as percentage of total protein)				
		Albumin	Globulins			
			alpha-1	alpha-2	beta	gamma
		Before absorption				
Germ-free	5.3	49.5	12.4	5.7	29.5	2.9
<i>C. albicans</i>	4.7	52.3	9.3	9.3	23.3	5.8
Conventional	6.3	38.3	8.0	6.2	35.8	11.4
		After absorption				
Germ-free	4.0	47.7	11.5	5.3	31.8	3.2
<i>C. albicans</i>	3.5	54.5	10.2	4.6	25.0	6.4
Conventional	4.6	39.0	8.8	7.1	33.6	11.5

\* The animals were about 12 months of age.

Because living as well as dead bacteria and other micro-organisms present in the food of animals may stimulate the synthesis of immunoglobulin, our diet was examined before it was autoclaved: total microbial counts were  $10^4$ – $10^6$  cells/g diet (dry weight) and viable counts were  $10^2$ – $10^3$  colonies/g.

The decreased concentration of gamma-globulin in germ-free mice agrees with other reports for various animal species. Thus a mechanism exists for the transport of antigenic molecules from the alimentary tract to the sites of antibody synthesis. As with bacteria, the establishment of *C. albicans* in the gut induces synthesis of gamma-globulin and possibly other immunoglobulins. Thus a function of the intestinal microflora is to provide the stimulus for a system of defence against infection. In addition, this stimulus can be dead micro-organisms in the diet, as mentioned, or other antigens in crude diets such as we used. Even highly purified diets can serve as such a stimulus<sup>5</sup>. Absorption of antigen from the intestine in young germ-free pigs depended on the levels of antigen in the gut; also, unless intestinal bacteria penetrated the host tissues no antibodies against these bacteria could be detected<sup>14</sup>. In some respects, their results are in contrast with those of others<sup>1</sup> who found antibacterial antibodies in several species of germ-free animals; these antibodies were bactericidal against *Escherichia coli*, *Shigella dysenteriae* and *Salmonella typhosa*. The serological patterns manifested by various species of germ-free animals have been described in several reviews and symposia some of which also deal with other aspects of gnotobiology<sup>12-17</sup>.

To sum up, values for total serum protein were similar in germ-free and conventional mice. The former had decreased levels of beta- and gamma-globulin and increased albumin. Association of *Candida albicans* with germ-free mice from birth to 12 months of age resulted in a progressive increase in gamma-globulin concentration, but this was less than that of the conventional animal at

12 months. Most abundant in these 1 month old mice was alpha-2-globulin and in 6 and 12 month old mice it was albumin. After absorption of serum with *C. albicans* cells the gamma-globulin level was decreased only in serum from bacteria-free mice associated with *C. albicans*. No infection was seen in these animals.

We thank J. McFadden and R. Woodward for keeping the germ-free mice. This investigation was supported by a research grant from the National Institute of Arthritis and Metabolic Diseases, U.S. Public Health Service.

## Allografts and Xenografts of Oviduct to the Cheek Pouch of the Syrian Hamster

ATTEMPTS<sup>1-3</sup> to transplant oviduct tissue have been relatively unsuccessful with one notable exception<sup>4</sup>. Successful transplantation of rabbit oviduct segments to the hamster cheek pouch has, however, been reported<sup>5</sup>. Further experiments have been conducted to refine the technique. Since this investigation, we have also used the cheek pouch successfully for transplantation and physiological studies of the uterus<sup>6,7</sup> and anterior pituitaries<sup>8</sup>. The transplantation terminology used here is that proposed by Snell<sup>9</sup>.

Oviducts were dissected from hamsters anaesthetized with 'Nembutal' after ligation of the utero-tubal junction and the ovarian end of the oviduct. Entire oviducts were dissected from rabbits killed by cervical dislocation or from dairy cows at the university abattoir. In each instance, the tissues were placed directly into a prophylactic bath<sup>6</sup> modified from that used by Billingham and Silvers<sup>10</sup>. Additional attempts were made to achieve a sterile technique during this procedure. Excess connective tissue was trimmed off and fine nylon threads were tied around the rabbit and cow oviducts in order to obtain doubly ligatured segments (3–12 mm long). Only segments of the middle region of the cow oviduct were used. Each host received two transplants (one to each pouch), both of which were from the same donor. Grafts were removed at various times up to 21 days after transplantation. After removal of the first transplants (first series), certain animals received allografts or xenografts as second transplants (second series). In the work with hamster and rabbit oviducts we tried to have at least two hosts, which were castrated males and females, treated with oestrogen or progesterone. Otherwise at least one host (male and female) was used with gonads intact or

as a castrate-untreated host. Oestradiol benzoate, 0.2 µg/0.1 ml. of corn oil, or progesterone, 2.0 mg/0.1 ml. of corn oil, was injected subcutaneously daily beginning 1 or 7 days after transplantation and continuing until the transplants were removed. Castrates treated with progesterone received a priming dose of oestradiol benzoate (0.2 µg) on day 1 or 7. Gross observations by transillumination were made at various intervals to evaluate the vascularity, health, turgidity and translucency of the transplants. Histological examination of each transplant was made.

In all, 168 transplants were recovered (150 first series plus 18 second series). Table 1 shows the number of grafts which survived in relation to treatment. Polymorphonuclear leucocytes were associated with less than 9 per cent of the grafts and interstitial red blood corpuscles were present in 22 per cent of the grafts. Infiltration of the peripheral portions of the transplants with mononuclear leucocytes was seen in the majority of grafts, especially those that were 12–21 days old. Survival of endosalpinx, evaluated histologically, was indicated when endosalpinx was present and intact around the entire lumen wall. There was a variable degree of connective tissue in all grafts whether or not the endosalpinx was degenerate. When viewed by transillumination, a rich blood supply to all portions of a graft was observed within two weeks of transplantation; also, all transplants possessing turgidity and translucency, the result of fluid production by the endosalpinx, showed survival of endosalpinx histologically. The absence of these two features, however, was not always related to degenerate endosalpinx.

Table 1. CONDITIONS OF ENDOSALPINX AFTER 12–21 DAYS AS ALLOGRAFTS AND XENOGRAFTS (FIRST SERIES) TO THE HAMSTER CHEEK POUCH

Donor tissue	Treatment group	No. of transplants		No. of transplants with non-degenerate endosalpinx	
		Male	Female	Male	Female
Hamster	Intact	2	6	2	6
	Untreated	2	2	2	2
	E-1	2	4	2	4
	E-7	2	8	2	4
	P-1	0	4	0	4
	P-7	4	4	1	2
Rabbit	Intact	2	10	2	7
	Untreated	2	2	1	0
	E-1	6	4	6	2
	E-7	5	2	3	2
	P-1	4	2	2	0
	P-7	2	4	1	3
Cow	Intact	0	7	0	0
	E-1	0	4	0	0
	P-1	0	2	0	2
	P-7	0	2	0	2

Intact, gonads intact; untreated, castrate and no injections; E-1, P-1 injections of EDB (E) or progesterone (P) begun on day 1; E-7, P-7, injections of EDB (E) or progesterone (P) begun on day 7; male, female, sex of host.

Except when otherwise stated, the following figures refer to first and second series allografts and first series xenografts that were 12–21 days old. Survival of endosalpinx was very low in 1–11 day old hamster and rabbit grafts: 8 per cent (1/12) and 13 per cent (5/38), respectively. In 12–21 day old grafts, the corresponding survival rates were 82 per cent (41/50) for hamster, 67 per cent (30/45) for rabbit and 15 per cent (2/13) for cow transplants. Rabbit ampullary tissue, however, gave the same survival rate (81 per cent, 29/36) as the allografts, whereas only 11 per cent (1/9) of the isthmus segments survived. In most instances, either the endosalpinx survived or was degenerate in both transplants to an animal. This was true in 92 per cent (21/26) of the hamster and 82 per cent (33/40) of the rabbit pairs. All second series allografts after first series allografts survived (6/6) while only 25 per cent (2/8) of the second series xenografts after first series xenografts survived. All allografts that followed xenografts survived (4/4).

Survival rates of hamster and rabbit endosalpinx in the intact animals were 100 per cent (8/8) and 75 per cent (9/12), respectively. The castrate-treated animals, with

hormone injections which started on day 1 and day 7, gave the following results: 100 per cent (10/10) and 50 per cent (9/18) for allografts; 62 per cent (10/16) and 69 per cent (9/13) for rabbit grafts. Treatment with oestradiol benzoate and progesterone gave these results: 80 per cent (16/20) and 75 per cent (15/20) for allografts; 77 per cent (13/17) and 50 per cent (6/12) for rabbit grafts. Survival in male hosts was 73 per cent (24/33) and 69 per cent (36/52) in female hosts.

Lumina of degenerate transplants (1–11 days old) were filled with atrophic epithelial cells. The few endosalpinx cells present were strongly basophilic and formed a simple, squamous layer. After 12 days, the epithelium varied from squamous to pseudostratified columnar and the taller cells showed secretory or luteal phase histology in response to hormone injections. We suggest that the degenerate epithelium of the 1–11 day old grafts was a result of inadequate circulation and that the epithelium 12–21 day old grafts resulted from proliferation and differentiation of intact squamous cells after an adequate blood supply had been established. It is probable that oviduct grafts can survive throughout the life of the host since long term (3–4 months) uterine allografts had intact endometrium and little or no appearance of tissue rejection<sup>8</sup>.

It was concluded that this transplantation procedure is a satisfactory technique for allografts of hamster oviduct and xenografts of rabbit ampullary oviduct segments, and that oviduct fluid is produced by endosalpinx in the absence of a nerve supply, or ovarian hormones, and even in the presence of testicular hormones. It is probable that this technique can be used to study transplants of other reproductive tract tissues such as rat and mouse oviducts, mouse uteri, and ovaries or portions thereof from various species.

### Inhibition of Delayed Hypersensitivity in Guinea-pigs after Competition between Synthetic Antigens

It has been shown previously<sup>1–3</sup> that immunological responses to protein antigens can be inhibited by administration in advance of large quantities of unrelated proteins. A similar inhibition can also be produced when two antigens are given simultaneously in the same emulsion of Freund's adjuvant<sup>4,5</sup>. Competition between antigens occurs when synthetic antigenic determinants of different specificity attached to the same non-antigenic protein molecule are injected into rabbits<sup>6</sup>.

It seems, therefore, that competition of antigens is a rather general biological phenomenon<sup>5</sup>. It is not, however, established whether the competing material must be itself antigenic in the test animal or at what stage of the immunization process competition of antigens takes place.

All the experiments were performed on inbred guinea-pigs of (Sewall Wright) strain 2 of the National Institutes

of Health stock. The following substances produced and characterized by the Weizmann Institute were used. Poly-L-lysine conjugated with dinitrophenyl (DNP-PLL); an optical L-isomer of the synthetic polypeptide containing tyrosine, glutamic acid and lysine in molar proportions of 6 : 55 : 39 respectively (252-L-TGL) (ref. 7); an optical D-isomer of the same polypeptide containing the same proportion of amino-acids (6 T : 55 G : 39 L) (251-D-TGL) (ref. 7); a synthetic polypeptide containing tyrosine, alanine and lysine in molar proportions 1 : 7 : 24 : 7 : 1 respectively (33 T-A-L) (ref. 8).

Antigenicity of these products has been investigated<sup>7</sup>. Thus, 252-L-TGL is antigenic for non-inbred Hartley guinea-pigs whereas 251-D-TGL is not. DNP-PLL and 252-L-TGL are antigenic for the strain 2 guinea-pigs; the products 251-D-TGL and 33 T-A-L are not antigenic in this strain (unpublished results of Ben Efraim).

Delayed hypersensitivity was induced by injecting into the hind footpads of the animals 0.4 ml. of an emulsion containing equal parts of complete Freund's adjuvant ('Difco') and of a solution in saline of various quantities of one or two of the synthetic antigens. Evaluation of the intensity of delayed hypersensitivity was made by measuring the skin reactions after intradermal challenge injections of the same products 10 days after immunization. Skin reactions were inspected after 3, 6, 24 and 48 h. All reactions were of the delayed type negative at 3 and 6 h and positive at 24 and 48 h. In Table 1 reactions are expressed by the mean diameter in mm, 24 h after the challenge injection.

Table 1. EFFECT OF COMPETITION BETWEEN SYNTHETIC ANTIGENS ON THE DEVELOPMENT OF DELAYED HYPERSENSITIVITY

Group No.	Quantities ( $\mu$ g/animal) of the substances injected	Delayed cutaneous reactions		
		Product† injected	No. of guinea-pigs Total	Mean diameter (mm) Pos-ster

		252-L-TGL	5	0 0

\* Diameter more than 5 mm.

† Concentration of DNP-PLL was 10  $\mu$ g/0.1 ml.; concentration of 252-L-TGL, 251-D-TGL and 33 T-A-L was 50  $\mu$ g/0.1 ml.

The products DNP-PLL and 252-L-TGL are powerful antigens, because 10  $\mu$ g of each of them incorporated in Freund's complete adjuvant produced by 10 days a state of delayed hypersensitivity which was evidenced by good delayed cutaneous reactions (groups 1 and 4). On the contrary, the product 251-D-TGL and the product 33 T-A-L, when injected in a dose of 600  $\mu$ g, failed to induce any detectable state of delayed hypersensitivity: all guinea-pigs tested 10 days after the injection of these substances remained negative (groups 6 and 7).

The second part of this table (groups 8 to 13) shows the results of the experiments in which guinea-pigs were injected with an emulsion containing two of the products, in various proportions, incorporated in Freund's adjuvant. The findings of these experiments may be summarized as follows. (a) When a large quantity of the antigen DNP-PLL is mixed with an immunizing dose of 252-L-TGL, the development of delayed hypersensitivity to the second antigen is inhibited (group 8). (b) When a large quantity of 252-L-TGL is injected with a small dose of DNP-PLL,

development of delayed hypersensitivity towards both of these antigens is impaired (group 9). (c) When a large quantity of the non-immunizing product 252-D-TGL is mixed with a minimum immunizing dose of 252-L-TGL, development of hypersensitivity to this antigen is entirely inhibited (group 10), but it is only partially inhibited if the immunizing quantity of 252-L-TGL is larger (100  $\mu$ g) (group 11). If the same product 251-D-TGL is injected with the DNP-PLL (10  $\mu$ g), the development of hypersensitivity to this antigen is not affected (group 12). (d) When a large quantity of the non-immunizing product 33-T-A-L was mixed with 10  $\mu$ g of the antigen 252-L-TGL, the development of delayed hypersensitivity to this antigen is not affected (group 13). It seemed to be rather enhanced, for these animals reacted as strongly as those of group 3 which were immunized with 100  $\mu$ g of 252-L-TGL.

The guinea-pigs of the last group (14) were injected with the same quantity of Freund's adjuvant alone and tested 10 days later with the antigen used. There was no reaction, which demonstrated that delayed cutaneous reactions to these antigens were highly specific.

Specific amino-acid polymers are very convenient for examination of the phenomenon of competition of antigens, because antigenic determinants are chemically well characterized and confusion from possible cross-reactions can be avoided. Furthermore, it could be possible to decide whether competing antigens must be chemically related (although immunologically non-cross-reacting) or if any antigen could compete with another.

Our results show that synthetic antigens may compete with each other as well as the protein antigens previously investigated<sup>1-4</sup>. It is noteworthy that 600  $\mu$ g of DNP-PLL, which showed a stronger antigenicity than 252-L-TGL (of groups 4, 2 and 5), produced a severe inhibition of reactivity to the latter (group 8), whereas when the injected quantities of these antigens were reversed (group 9), the inhibition of the reaction to DNP-PLL was only partial.

More interesting are the results produced by the products 251-D-TGL and 33 T-A-L. These substances when injected alone do not produce any detectable state of delayed hypersensitivity (groups 6 and 7), and thus cannot be considered as antigens. Nevertheless, when 600  $\mu$ g of the D isomer, 251-D-TGL, is injected together with 10  $\mu$ g of its L-isomer (group 10), it entirely inhibits skin reactivity to the latter. It would seem, therefore, that certain non-antigenic substances mixed with antigens could compete and inhibit immunization. It is now known, however, that when some oligopeptides of D-isomers are attached to non-antigenic protein molecules, they can stimulate immuno-competent cells, that is, they can be recognized as antigens by these cells, and induce production of specific antibodies, which do not cross-react with the L-isomers of these oligopeptides<sup>9,10</sup>. If the whole molecule was constituted by D amino-acids there was no antibody formation or development of delayed hypersensitivity (group 6), but this may be because the immunization process was blocked in some stage other than antigen recognition. Consequently, the finding that the D-isomer can inhibit immunization to its L-isomer suggests that the immunologically competent cells may recognize both substances as "antigens".

The same does not apply in the case of the product 33 T-A-L. This substance is not antigenic in the strain 2 guinea-pigs, although it is a good antigen in rabbits<sup>7</sup>. Our results show that when a large quantity of 33 T-A-L is injected with a minimum immunizing dose of 252-L-TGL, immunization of the animals towards this antigen is not affected (group 13).

It can be concluded, on the basis of these results, that competition in immunization only occurs between substances recognized as antigens, and that this competition takes place during the state of recognition by the immunologically competent cells.

We thank Professor M. Sela of the Weizmann Institute for the synthetic products used in these experiments. J. Cunningham provided technical assistance.

## PHYSIOLOGY

### Movement of Glucose and Sodium Chloride from the Oropharyngeal Cavity to the Brain

OROPHARYNGEAL stimuli evoked during tasting, chewing and swallowing of food have been shown to influence the rate and degree of ingestion<sup>1,2</sup>. The "satiety mechanism" seems, however, to be operative only if ingesta enter the stomach. It has been reported that animals which have been depleted of sodium or water consume sufficient quantities to compensate for deficits. The observation of animals satiating their appetite in a few minutes, or by a single ingestive act, before absorption from the intestine is likely has led several investigators to postulate some sort of oropharyngeal metering<sup>3,4</sup>.

During the oral phase of ingestion, information from nutrients may be transmitted directly from the oropharyngeal cavity to brain structures associated with the mediation of consumption. Whether the mediation of the ingestive response occurs through neural, humoral or a combination of pathways has not been determined. Furthermore, little consideration has been given to the possibility that rapid transmission of humoral information from the oropharyngeal cavity to the central nervous system (CNS) could be of consequence for ingestion before feedback from post-ingestion occurs. Support for this idea is provided by the observation that absorption of chemical compounds has been shown to occur from the oropharyngeal cavity into the circulatory system<sup>5,6</sup>. Moreover, greater activity has been found in the brain samples of deficient rats administered magnesium-28 intraperitoneally than in replete animals, which suggests a selective movement of depleted nutrients to the CNS<sup>7</sup>.

In experiments to determine whether glucose and sodium chloride would pass from a ligatured oropharyngeal cavity to the brain, a total of eighteen male Holtzman rats, weighing 380–470 g, maintained on an *ad libitum* food and water regimen, were used. The animals were anaesthetized with chloral hydrate (400 mg/kg, intraperitoneally). The oesophagus and trachea were securely ligatured medial to the submaxillary glands. A tracheal cannula was inserted posterior to the ligature, and the animals were mounted in an upright position by means of a head holder.

In experiment 1 glucose labelled with carbon-14 (5  $\mu$ c./0.5 ml.) mixed in a 2 per cent solution of glucose, and oleic acid labelled with carbon-14 (0.25  $\mu$ c./0.05 ml.) in a 2 per cent solution of oleic acid, were used. In experiment 2 glucose labelled with carbon-14 (6.25  $\mu$ c./0.25 ml.) was

used, and in experiment 3 sodium-24 (14.8  $\mu$ c./0.25 ml.) in a 0.96 per cent sodium chloride solution was used. Samples of 250  $\lambda$  of the isotope (250  $\lambda$ ) solutions were placed into the oropharyngeal cavity. Several animals received the isotope solutions into the initial portion of the duodenum.

Blood samples were obtained by cardiac puncture just before decapitation, at the end of the period of isotope application. During the removal of the brain from the cranium, the head was maintained with the mouth held in a downward position to prevent contamination from any radioactive material remaining in the oropharyngeal cavity.

In the experiments with labelled glucose the complete liver was removed and analysed. The times were noted to the nearest second for the period of isotope application. The exposure time refers to the time period beginning with the introduction of the isotope until the removal of the tissue samples. The counting procedure used for the labelled glucose involved a modification of the dry flask combustion technique<sup>8</sup>. An NMC model 4A proportional gas flow counter was employed (counter efficiency of 34 per cent) to count the labelled barium carbonate planchets. Each sample was counted ten times for 500 sec. Corrections were used for background, counter efficiency and self-absorption.

The application procedure for the labelled sodium chloride was similar to treatment with labelled glucose. After the death of the animals the "wet" sample weights were obtained and counting was recorded with a 200-channel RIDL pulse height analyser in conjunction with a 3' x 3' well-type thallium doped crystal of sodium iodide as the detector<sup>9</sup>. Counts of the samples were taken for either 20- or 30-min periods, depending on the level of activity. The area under the 1.38-MeV sodium-24 peak was compared with a standard in order to determine the activity in each sample. Corrections of the activity were made for background and crystal efficiency. The samples were dried and the weights obtained. The initial experiment involved the use of labelled glucose and labelled oleic acid. An oral application time of 5 min was used. Table 1 shows the treatments, exposure time, per cent uptake, and the disintegrations/sec/g of wet sample weight.

Table 1. ACTIVITY OF LABELLED GLUCOSE AND LABELLED OLEIC ACID OBTAINED WITH A 5 MIN OROPHARYNGEAL APPLICATION

Treatment	Measurement	Brain	Liver	Blood
Glucose	D.p.s./g*	113.6	0.03	1.01
	Exposure time (min)	14.0	10.0	6.00
	Percentage uptake	$1.98 \times 10^{-2}$	Nil	$0.05 \times 10^{-2}$
	D.p.s./g	79.0	0.09	0.19
	Exposure time (min)	15.0	9.0	7.0
	Percentage uptake	$2.37 \times 10^{-2}$	$0.09 \times 10^{-2}$	$0.33 \times 10^{-2}$
Oleic acid	D.p.s./g	Nil	Nil	0.061
	Exposure time (min)	13.0	8.0	6.00
	Percentage uptake	Nil	Nil	$0.21 \times 10^{-2}$
	D.p.s./g	2.4	0.27	0.30
	Exposure time (min)	14.0	9.0	5.00
	Percentage uptake	$0.10 \times 10^{-2}$	$0.10 \times 10^{-2}$	$0.21 \times 10^{-2}$
Control for background activity	D.p.s./g	Nil	Nil	Nil
	Exposure time (min)			
	Percentage uptake			

\* Obtained on a wet weight basis: dry weights were not taken.

Substantial activity appeared in the brain with the oral administration of labelled glucose, but little or no activity with the labelled oleic acid. It should, however, be noted that the level of activity in the oleic acid was lower than that of the glucose. Relatively little activity was detected in the wet samples of the liver or blood after the oral administration of the isotope.

In a second experiment the glucose treatments were repeated with exposure for 1, 3 and 7 min. Additional controls employing duodenal administration were added. The exposure time of the blood samples indicates the period

Table 2. ACTIVITY OF LABELLED GLUCOSE OBTAINED WITH A 1, 3, OR 7 MIN OROPHARYNGEAL OR DUODENAL APPLICATION

Treatment	Measurements	Brain	Liver	Blood
Oral	D.p.s./g*	71.5	13.1	Nil

	Percentage uptake			

\* Obtained on a dry weight basis.

of application. Table 2 summarizes the data. The activity in the liver was substantial in the case of intestinal administration of the sugar. Only after oropharyngeal administration of the labelled glucose was substantial activity in the brain detected.

A third experiment was undertaken using labelled sodium to determine whether the movement of labelled glucose or its metabolites to the brain was limited to this nutrient or represented a more general phenomenon. Operative procedures similar to those previously described were carried out and the results are presented in Table 3.

Table 3. ACTIVITY OF LABELLED SODIUM CHLORIDE OBTAINED WITH 3 AND 8 MIN OROPHARYNGEAL OR DUODENAL APPLICATION

Treatment	Measurements	Brain
Oral	D.p.s./g*	1,866.2

\* Obtained on a dry weight basis.

Examination of the activity described in Table 3 indicates that sodium-24 passes from the mouth to the brain. Furthermore, for the time periods investigated, activity of sodium-24 in the brain samples was substantially greater when administered by mouth than through the duodenum.

Activity from labelled glucose and labelled sodium chloride was detectable in the brain after the isotopes were placed into the ligatured oropharyngeal cavity. The levels in the brain exceeded those found in the circulation. Some activity from these substances was detected in the brain after introduction into the intestine, but it was of a substantially smaller magnitude. The activity of carbon-14 which was measured could represent an accumulation of glucose or glucose metabolites. The experiments with labelled sodium chloride indicated also that, after oropharyngeal placement, this isotope moved very rapidly to the brain in greater concentrations than after intestinal administration.

The data obtained do not indicate the pathway of the isotopes. The glucose and sodium chloride could have been absorbed and moved through the circulatory system, to the heart and then back to the brain. An alternative would be a direct passage through special pathways from the oropharyngeal cavity to the brain. The low level of activities detected in the blood gives some support to the idea of a direct pathway.

The movement of small quantities of nutrients from the oropharyngeal cavity to the brain could be of special significance in the detection and monitoring of ingesta before feedback from post-ingestion can occur. The volume of food and fluid consumed by mammals has been shown to be mediated partly by subcortical structures located at the base of the brain<sup>10</sup>.

### Concept of Micro-environment related to the Regional Cytology of Lymph Nodes

It is a matter of common observation that in the lymph node of the older animal each of the subdivisions of the lymphoid pulp, namely, centron<sup>1</sup>, cortex and medullary cord, maintains a different type of population. The centron may have a high population of blast cells; the cortex remains predominantly composed of small lymphocytes, and the medullary cord specializes in plasma cells.

These area peculiarities of the lymphoid pulp are maintained in spite of the high probability that lymphoid cells are continually moving from region to region. It is true that fixed macrophage barriers seem to exist between these regions<sup>2</sup>, which are capable of trapping lymph-borne particles<sup>1,2</sup>, but these loose structures can scarcely be regarded as a bar to the amoeboid movement of lymphoid cells. A further complication is the constant stream of small lymphocytes emerging from venules<sup>4</sup>.

If the area populations are so constantly maintained in spite of almost certain cellular contamination from outside, a logical way to account for the findings is to suppose that these regions all have a different stromal micro-environment.

According to this concept, the centron, cortex and medullary cord are each little worlds of their own. Each environment governs the population of lymphoid cells which reside in it or have recently invaded the region. A complex kinetic equilibrium is produced, to which cell division, interconversion and inter-regional movement all contribute. The end result is a stable population, which is different for each region.

Can it be shown that these areas of pulp have different micro-environments? If two matters—relative antigen concentration and blood supply—are considered, a reasonable case can be made out for such differences.

First, in respect of relative antigen concentration, Nossal *et al.*<sup>5</sup>, in their investigations of the distribution of afferent lymph-borne antigen marked by radio-iodine in various regions of the lymph node, have shown a high concentration of antigen in the centron macrophages, a low concentration in the cortex, and a high concentration in all medullary structures (Fig. 1).

To this antigen environmental parameter can be added another, namely, blood supply. I have re-investigated<sup>8</sup> this, using aortic injection of 10 per cent gelatine in indian ink to show vascular patterns in para-aortic lymph nodes. The technique, and the patterns produced by it, have been discussed in detail elsewhere<sup>6</sup>.

Two important points arose from these vascular studies. First, the centron is an almost exclusively capillary body. Afferent arterioles arborize into capillaries in the immediately neighbouring cortex, but do not penetrate the centron itself. Large cortical venules can be observed in the immediate vicinity, but rarely within the centron sphere (Fig. 2).

Second, the medullary cords nearly always contain a large, central, very thin-walled venule (Fig. 2). Arterioles are found only occasionally in the cords; venules far outnumber them.

The combination of the two environmental parameters is summarized in Table 1.

Table 1

	Local antigen concentration	Local blood supply	Predominant cell
Centron	High	Capillary	Blast cell
Cortex	Low	Arterio-venous	Small lymphocyte
Medullary cord	High	Venous	Plasma cell

Examination of Table 1 leads to the thought that there may be a mitogenic factor in arterial blood, which diffuses progressively from capillaries and venules. This factor can be supposed to operate only in synergism with a high local antigen environment. In the cortex it is inoperative for this reason, and the population in this area, therefore, remains composed of small lymphocytes.

In the presence of a local high concentration of antigen, the diffusing haematogenous factor produces two types of result, depending on its local perivascular concentration. If this concentration is high, the effect is to encourage cell division, producing large numbers of local blast cells with a high mitotic count. If its concentration is low, the effect is to encourage the production of protein, with the resultant local appearance of plasma cells. This vascular factor thus explains the different lymphoid population of centron and medullary cord, in spite of the fact that they are both high antigen areas.

A gradient of diffusible factor, higher at the arterial, lower at the venous end, could occur around a long venule, such as the straight central venule of the medullary cord. This might account for Sainte Marie's observation<sup>7</sup> that plasma cells which he classifies as immature

Fig. 2. Section of cortex and medullary cords of 200 g rat with well formed follicles. The vessels have been injected with 10 per cent gelatine in indian ink, as mentioned in the text. This is essentially the venular pattern. In this preparation, capillaries and arterioles are not seen. Note (a) complete absence of major venules in follicles; (b) anastomosing, wide-bore venules in cortex; (c) bottom left, a straight venule passing through the centre of a medullary cord. Haematoxylin and eosin. Gelatine section cut at  $20\mu$  ( $\times 90$ ).

are found more at the outer end of the cord than towards the hilum. My experience with various types of antigen stimulation has confirmed that this outer-inner maturation gradient in the cord is a frequent finding.

So much for the existence of a hypothetical diffusion factor from the blood. What is certain is that centron, cortex and medullary cord do seem to have different micro-environments. This cannot be without effect on their contained lymphoid populations.

## Physiological Adaptation and Partial Dormancy in *Ascaris* Eggs

PHYSIOLOGICAL adaptation of the rates of life processes in response to changes in environmental temperature is now known to be commonplace in poikilothermic organisms<sup>1</sup>. Animals, plants and micro-organisms experimentally subjected to a change in temperature within normal viable limits initially show modified rates of metabolic functions which, in the absence of "overshoot", accord with predictions based on chemical kinetics. In many cases, however, these rates either decrease (rise in temperature: " $T+$ " adaptation) after the first phase or increase (fall in temperature: " $T-$ " adaptation) slowly over a period of days or weeks, eventually attaining a new constant value which tends towards the rate characteristic for the original temperature. The nearer the correspondence the more highly adaptable is the organism in that particular respect<sup>2</sup>. Such slow modifications are generally considered to be true physiological adaptation (that is, "capacity adaptation") in contrast to the rapid changes (overshoots) which are completed in a matter of minutes or hours after the change in temperature.

Overshoot phenomena may be related to neuromuscular physiology<sup>3</sup> or, at the cellular level, to the rate of attainment of new steady states dependent on diffusion processes<sup>4</sup>. The biological significance of true physiological

Fig. 1. Section of cortex of rat lymph node, containing afferent lymph-borne flagellar antigen marked by radio-iodine. The antigen has concentrated in the region of two follicles. The rest of the cortex contains virtually no antigen. The medullary structures, seen as a zone at the bottom of the preparation, are densely marked. Preparation supplied by courtesy of Professor Nossal, Walter and Eliza Hall Institute, Melbourne. Methyl green-pyronin. Paraffin section cut at  $7\mu$  ( $\times 90$ ).

adaptation, Precht's<sup>2</sup> "resistance" adaptation apart, is less easy to evaluate. Studies so far have mostly concerned actively metabolizing organisms in which it seems likely that adjustments of this kind further a better integrated rate pattern throughout a complex series of processes.

This communication suggests that physiological adaptation of the capacity type to temperature change may acquire a new significance in the evolution of some dormant mechanisms, and that stages of organisms having metabolic characteristics approaching dormancy may provide ideal tools for the study of physiological adaptation.

In living things with no immediate energy requirement, whose energy sources are endogenous and finite, and whose success is proportional to survival time, selection in favour of reduced metabolic rate would be expected. A mechanism ready to hand for such selection is the  $T^+$  adaptation outlined earlier—which would be selected at the expense of the converse, that is  $T^-$  adaptation. The suggestion obviously presupposes independent physiological and genetic control for the two processes; a possibility not contradicted by the available evidence.

Structures likely to be subjected to these selection pressures include protozoan cysts and the eggs and larvae of some metazoan parasites. Useful experimental material is likely to be found among these forms, because metabolism, though reduced, can be measured by conventional means<sup>5,6</sup>.

A test for temperature adaptation is the measurement of a rate function at the same temperature of two populations of an organism acclimated to two different temperatures. A difference between rates under these conditions is evidence for the thesis, provided no reproduction has occurred and no physiological damage has resulted from the temperature treatment itself.

The infective eggs of the pig parasite, *Ascaris suum* (Nematoda), exhibit partial dormancy in that they have a low  $Q_{O_2}$  (ref. 5) and can survive for long periods without exogenous energy sources<sup>7</sup>. Dormancy is broken when the temperature rises above 36°C, together with changes in pH, carbon dioxide concentration and redox potential<sup>8</sup>.

Table 1.  $Q_{O_2}$  AT 35° C OF ACCLIMATED INFECTIVE *Ascaris* EGGS

Hours of measurement	Eggs acclimated to 25° C ( $\mu\text{l./mg/h}^*$ )	Eggs acclimated to 30° C ( $\mu\text{l./mg/h}^*$ )
First	0.351 $\pm$ 0.026	0.201 $\pm$ 0.015
Second	0.399 $\pm$ 0.019	0.224 $\pm$ 0.037
Third	0.357 $\pm$ 0.018	0.233 $\pm$ 0.022
Fourth	0.365 $\pm$ 0.031	0.223 $\pm$ 0.045
Fifth	0.393 $\pm$ 0.010	0.229 $\pm$ 0.028
Means	0.374 $\pm$ 0.020	0.221 $\pm$ 0.029

\* Combined data from three experiments: means and standard deviations. Individual determinations made in triplicate 5 ml. Warburg flasks containing 70–100 mg dry weight of freshly washed eggs in 1 ml. 0.1 normal sulphuric acid per flask.

Warburg measurement of the oxygen uptake at 35°C of "de-coated"<sup>9</sup> infective *Ascaris* eggs acclimated previously to 25°C and 30°C for 11 days shows adaptation to be well developed (Table 1). The  $Q_{O_2}$  at three other temperatures confirms these observations and shows translation and rotation of the  $R-T$  plots<sup>1</sup> (Fig. 1). The eggs used in these measurements were incubated to the infective stage at 25°C for 39 days in 0.1 normal sulphuric acid before acclimation. All temperature treatments were carried out in the same solution in water baths at constant temperature equipped with shakers operating at 100 oscillations/min. The eggs suffered no damage from acclimation experiments, as was shown by hatching trials using the physiological methods of Fairbairn<sup>8</sup>. Approximately 90 per cent of the fertile eggs (2–3 per cent were infertile) hatched, and there was no significant difference after acclimation to either temperature.

Chemical analyses were also made of eggs before and after acclimation to assess the economic advantage conferred by the adaptation demonstrated in metabolic rate.

No significant difference emerges between eggs acclimated to the two temperatures in regard to total dry weight, nitrogen as protein, total lipid, or carbohydrate (for methods, see ref. 6). A significant increase in the content of alkali-stable carbohydrate (ACHO—glycogen plus trehalose), however, occurs after acclimation to both temperatures compared with eggs before acclimation (Fig. 2). Such synthesis probably utilizes lipid carbon<sup>10</sup>.

Assuming that adaptive decrease in metabolism is linear with time, and that carbohydrate synthesis is proportional to the utilization of energy reserves, an approximate estimate of economic advantage can be made. Values of the ratio

$$\frac{\text{percentage increase in ACHO}}{\text{mean } Q_{O_2}}$$

were 140 and 120 for eggs acclimated to 25°C and 30°C respectively. From the mean value of 130 one can predict the approximate synthesis that would have occurred in the absence of adaptation, using the  $Q_{O_2}$  estimates for the non-acclimated eggs, that is,  $0.135 \times 130 = 18$  per cent (25°C) and  $0.251 \times 130 = 33$  per cent (30°C). The measured increases were 14 per cent (25°C), a "saving" of 22 per cent, and 18 per cent (30°C), a saving of 45 per cent. There is every reason to believe adaptation to be possible to even lower metabolic rates in such organisms, so that the economies shown to occur in 11 days' acclimation are slight compared with what would accrue over prolonged periods.

The analyses do not reveal the concurrent loss of lipid that would be expected, probably because the gravimetric lipid measurements were not precise enough to detect it (see Fig. 2). In any case, decrease in lipid would be expected to be only 50–60 per cent by weight of the carbohydrate synthesized from it.

Fig. 1. Berthelot plot of  $Q_{O_2}$  measurements ( $\mu\text{l./mg/h}$ ) of infective *Ascaris* eggs before (▲) and after acclimation to 25°C (●) and 30°C (▼) for 11 days. The data are from one experiment in which 10 min readings were made for 1 h at each temperature. Each point and vertical line is the mean  $\pm$  S.D. of triplicate 5 ml. Warburg flasks containing 60–70 mg dry weight of freshly washed eggs in 1 ml. 0.1 normal sulphuric acid per flask. The same samples were successively treated to stepwise increases in temperature in the Warburg bath and equilibrated for 15 min between each hour of measurement.

It is obvious that the adaptation shown to be possible in *Ascaris* eggs cannot be fitted into the categories described by Precht<sup>2</sup>, but it would be surprising if it could be. If one assumes an equilibrium between  $T^+$  and  $T^-$  processes to be the "normal" situation in metabolically active organisms, a selection pressure which emphasizes the former at the expense of the latter would tend to eliminate the equilibrium state and therefore result in a continuously declining metabolic rate at any temperature. This is consistent with the fact that *Ascaris* eggs, even though they were kept for 39 days at 25°C during their development to the infective stage, still showed a signi-

Fig. 2. Chemical composition of eggs before acclimation (left hand column of each set of three) and after 11 days acclimation to 25° C (centre columns) and 30° C (right hand columns). A, Total dry weight (black portion is sum of total solids measured independently); B, nitrogen as protein (that is  $N \times 6.25$ ); C, total lipid; D, total carbohydrate; E, alkali-stable carbohydrate (glycogen plus trehalose); F, glycogen. Numbers of eggs were determined with an automatic cell counter. Combined data from four experiments with 95 per cent confidence limits.

significant decline in  $Q_{O_2}$  when kept subsequently at the same temperature. Despite the "abnormal" nature of such adaptation, however, I suggest that infective *Ascaris* eggs, and similar living things, are particularly suitable for the analysis of these phenomena for the following reasons: a, there are no short-term fluctuations in metabolism related to behavioural phenomena to complicate measurements; b, reproduction, cell division and growth do not occur; c, there are no exogenous nutritive sources; and, d, the very abnormality may assist analysis if, as is proposed, only one of the two main aspects of temperature adaptation is present. Such an approach may also provide a new insight into the study of dormant mechanisms.

I thank the U.S. National Institutes of Health for financial support and Miss J. M. Dick for skilled technical assistance.

### Reduction-Oxidation Potential of Blood as a Function of Partial Pressure of Oxygen

ATTEMPTS to establish the reduction-oxidation potential of blood as a useful index in clinical medicine<sup>1</sup> have met with little success. Possibly the redox measurement of blood, despite its reasonable reliability<sup>2</sup>, is too crude an index for the changes which are likely to occur in the

many and complex interacting electron transport systems of the blood. On the other hand, the reasons for failure may be largely technical. Redox measurements of the blood have usually been carried out under unknown or uncontrolled conditions of pH and temperature, and in the presence of unknown partial pressures of oxygen in the blood. These variables could account for relatively marked changes in the redox measurement<sup>2</sup>.

The present investigation demonstrates the relationship between the redox measurements of the blood and the partial pressure of oxygen in the blood under known conditions of pH and temperature. As in our previous work<sup>3</sup>, the potential was measured by means of a gold electrode using a saturated calomel electrode as a reference cell. The only significant change introduced was the use of unbuffered citrated blood, and the measurement throughout the experiment of the partial pressure of oxygen and of pH. (The partial pressure of oxygen was measured by means of an oxygen macro electrode sealed into the blood chamber and connected to a physiological gas analyser. The pH was determined by removing anaerobically small portions of the blood sample for measurement in a Beckman 'Micro Blood pH Assembly'.) A magnetic stirrer kept the blood circulating. The temperature of the blood was constant at 37.4° C. Oxygen was expelled by bubbling pure argon through the blood.

Fig. 1. Relationship in the blood between reduction-oxidation potentials and partial pressures of oxygen during a period of time necessary to establish a steady final redox state.

Fig. 1 illustrates a representative finding of the relationship between the redox potentials and the partial pressure of oxygen over a period of 24 h. The pH of the blood was 6.8.

Section A of the graph shows that there is a positive, though not quite linear, relationship between redox measurements and partial pressure of oxygen. A reduction of the partial pressure of oxygen from 55 to 32 mm of mercury was associated with a concomitant steady reduction in the redox potential from -62 mV to -102 mV—a change of 1.7 mV/mm of mercury of the partial pressure of oxygen. Section A also shows that when the partial pressure of oxygen was held constant at 32 mm of mercury, the redox potential remained steady at -102 mV.

Section B of the graph shows that when deoxygenation of the blood was resumed, the redox potential again began to decline. When the partial pressure of oxygen reached zero, the redox potential was -202 mV. The redox potential of the blood was not, however, arrested at the point where the partial pressure of oxygen became zero. The even decline of the redox potential continued, and at about the same rate as before, until it reached a final

Fig. 2. Relationship between redox potentials and partial pressures of oxygen of the same sample of blood in two consecutive experiments. (A) Represents first experiment. Second experiment (B) was carried out after re-oxygenation of the blood. The final steady redox potential in both (A) and (B) was  $-416$  mV.

steady state of  $-370$  mV (section C). From the beginning of the experiment, it took approximately 20 h before the redox potential attained its final steady state.

Similar experiments were carried out with other samples of blood, and with the same sample of blood under altered conditions (such as previous freezing of the blood sample). All produced similar results. The relationship between the partial pressure of oxygen and redox potential was, however, found to vary considerably, even when the final steady redox states were the same. This is illustrated in Fig. 2 which shows the relationship between redox measurements and partial pressures of oxygen of the same sample of blood submitted to two consecutive experiments. The same final steady state was reached in both instances (redox potential  $-416$  mV), but the relationship between redox measurements and partial pressure of oxygen was quite different.

In summary, our experiments indicate that (a) there is a positive, but not quite linear, relationship between redox measurements and partial pressure of oxygen; (b) this relationship is not constant and varies greatly with certain experimental manipulations of the blood sample; (c) a steady partial pressure of oxygen is associated with a steady redox measurement; (d) complete deoxygenation of the blood initiates a steady, progressive decline in redox values which ordinarily do not reach a steady state for at least 10 h; and (e) the value of the final steady state cannot be accurately predicted from a redox measurement taken in the presence of oxygen. It would seem that redox measurements of the blood need to be made in conditions of complete deoxygenation and in known conditions of temperature and pH. Redox investigations carried out *in vivo*, or in the presence of oxygen, are likely to be of doubtful value.

## Differential Identification of Micro-organisms by Analysis of Phosphorescent Decay

THIS communication reports evidence for the existence of unique and characteristic components in the phosphorescent decay of individual strains, species and morphologies of various micro-organisms.

If observation of the decay is restricted to a particular energy of transition, that is, a particular emission wavelength, then for an array of radiators in the structure the physical origins of which will in general be different, the total intensity of radiation at any given time,  $t$ , will be expressed by a function of the form

$$I_T = I_0 \exp(-\lambda_0 t) + I_1 \exp(-\lambda_1 t) + \dots + I_n \exp(-\lambda_n t) \equiv \sum_i I_{i0} e^{-\lambda_i t} \quad (1)$$

and the form of this function will be valid irrespective of alternative decay paths or parent-daughter relationships between adjacent states if no restrictions are placed on the coefficients.

The biological samples in this experiment were prepared from five bacterial strains; namely, *Bacillus subtilis*, *Staphylococcus epidermidis*, *Neisseria meningitidis* Group A (strain 1027A), *N. meningitidis* Group B (strain L-1), and *N. meningitidis* Group B (strain 2091B).

All the samples were grown in modified Franz medium for 20–22 h at  $37^\circ$  C. After this period of growth the collected cultures were washed five times in a solution of 0.15 molar sodium chloride and then were collected by centrifugation. The *B. subtilis* and *S. epidermidis* were studied both as living organisms and as autoclaved whole cells, while the *Neisseria* cultures were killed by 1 per

Fig. 1. Plot of emission intensity versus emission wavelength for two intact organisms: A, *Bacillus subtilis*; B, *Staphylococcus epidermidis*.

cent  $\beta$ -propiolactone in which they were placed for 2 h at room temperature, followed by about 24 h at  $0^\circ$ – $4^\circ$  C.

In addition to the study of the structures of washed whole cells from each sample, preparations of the *Neisseria* strains were morphologically disrupted by alternate freezing and thawing at pH 7.0. The freed cell walls were cleaned by washing in saline solution, in phosphate-buffered saline, and finally in distilled water. The cell sap, on the other hand, was filtered through a membrane filter with a pore size of  $0.45\mu$ . The protein content of the cell wall suspensions and the cell sap was determined by the Lowry method and adjusted to uniform values before the analysis was begun.

Fig. 1 shows the total emission spectra for two whole cell samples. In both cases the x scale is linear,  $x_0 = 200$  mμ and each division is 50 mμ. The curve with multiple peaks is the total spectrum in which the first peak represents elastic scatter of exciting radiation, the second peak fluorescence and the third phosphorescence. The superimposed second curve shows the phosphorescent emission bands alone obtained by using a shutter to exclude scatter and fluorescent emission.

\* Uncorrected for variation of photomultiplier sensitivity with respect to changing  $\lambda$ .

† Red-shifted by 10 m $\mu$  as a result of an uncorrected monochromator.

Table 1 lists for each sample the excitation wavelength for the total emission and phosphorescent curves, the wavelength corresponding to the point of maximum fluorescence ( $x_f$ ), the wavelength corresponding to the point of maximum phosphorescence ( $x_p$ ) and the ratio of the maximum fluorescent intensity to the maximum phosphorescent intensity ( $F/P$  ratio). The spectra and maxima presented are not corrected for variation in the sensitivity of the photomultiplier to wavelength.

Fig. 2 shows the phosphorescent decay curves for the same samples plotted on a semilogarithmic scale. The dotted line envelope is the overall decay curve, the solid

lines show the individual components obtained by piecemeal subtraction. Alongside each component is its half-life, defined by the time required for the population of the state concerned to decrease to half its initial value.

Table 2 lists the values of  $\lambda_i$  for each component and each sample as well as the quantity  $T_{L \times 10^{-3}}$  defined by

$$T_{L \times 10^{-3}} = \frac{\ln 1000}{\lambda_i}$$

The analysis of total emission and phosphorescent spectra of the four micro-organisms and their substituents was highly reproducible from preparation to preparation in single organisms, and also showed distinguishing marks of emitting domains from one organism to another. The relative coincidence of the overall phosphorescent emission curves was obtained by calculating a constant  $kx_p'$  given by

$$kx_p' = \frac{x_{p_3} - x_{p_2}}{x_{p_3} - x_{p_1}} \quad (2)$$

The  $x_p$  values for cell saps of all strains of *N. meningitidis* were uniformly located at 445 m $\mu$  and appeared to be occurring singly although there was some indication of a shoulder at ~410 m $\mu$ . This very weak phosphorescent emission occurred after excitation at 310 m $\mu$ . An excitation maximum at 310 m $\mu$  for cell sap with an  $x_p$  of 445 m $\mu$  is uncommon and, so far as could be determined, is not typical of centres associated with protein.

We now draw attention to Fig. 1 and the emission spectra of whole cells of *B. subtilis* (Fig. 1A) and *S. epidermidis* (Fig. 1B). The general forms of the total

$\lambda_1$	0.385	0.693	1.595	1.155	1.260	1.540		1.260	0.533	0.866
$T_1L \times 10^{-3}$	17.95	9.97	4.33	5.98	5.48	4.49		5.48	12.96	7.98
$\lambda_2$	0.578	1.386							1.066	
$T_2L \times 10^{-3}$	11.95	4.98							6.48	
$\lambda_3$	1.98									
$T_3L \times 10^{-3}$	3.49									

and phosphorescent emission curves are different, if not indeed unique, from one species or strain to another. It is entirely possible that cellular substituents, such as cell sap which has its excitation maxima at 310 mμ, might reabsorb fluorescent radiation of the prime luminescent centre ( $x_f \sim 325$  mμ) and dissipate this energy in a characteristic fashion simultaneously with other discrete centres, thus giving a typical total emission curve for the species as an expression of the sum of all available processes concerned.

The alteration, for example, in the phosphorescent emissivity of *B. subtilis* was of considerable interest in view of its marked morphological difference from the other micro-organisms studied.

It will be seen from the decay curves (Figs. 2a and b) that the samples investigated differ both in the number of exponential terms required to produce the function,  $I_T$ , and in the decay constants,  $\lambda_i$ , associated with each term.

Figs. 2a and b show the decay curves of *B. subtilis* and *S. epidermidis*, respectively. We have found these functions to be characteristic of these two organisms, indeed constant, in a manner independent of whether these organisms were alive or autoclaved with steam as well as independent of the culture medium, preparation technique and concentration. It has been possible, as a result, to pick out samples of each of them blindly from a control batch. A salient feature of the two curves is the four component nature of the decay of *Bacillus subtilis* and the three component character of the *Staphylococcus epidermidis*. In addition, it can be seen that the components have significantly different decay constants associated with them (Table 2).

Thus, because of the nature of the function,  $I_T$ , it would appear possible to form a vector of the individual coefficients and decay constants of the form

$$S \equiv \{\lambda_0, \lambda_1, \dots, \lambda_n, I_0, I_1, \dots, I_n, x_{f1}, x_{p1}, I_{f\max}, I_{p\max}\}$$

such that

$$\sum_i I_i \exp(-\lambda_i t) \equiv I_T$$

and

$$\sum_i I_i \equiv 1$$

and where  $x_f$  and  $x_p$  are the wavelengths in the total emission spectra corresponding to maximum fluorescent and phosphorescent intensity respectively and  $I_f$  and  $I_p$  are those maximum intensities. It is recognized that the terms  $I_{f\max}$  and  $I_{p\max}$  depend on concentration and as such, under the present methods, will not be constants. It is clear, however, that these components can be used in calculation of quantities such as  $F/P$  ratios and the constant  $K_{xp}$  described here, which are, in fact, independent of the variable parameters of the analysis.

The data presented indicate that the molecular domains and the manner in which they dissipate absorbed energy can form a unique signature,  $S$ , of the specific organism or component under examination. Furthermore, comparison of such  $S$  vectors may permit identification of at least groups and perhaps individual components and organisms.

### Absence of Atherosclerosis in the Cerebral Arteries of Chickens fed an Atherogenic Diet

THERE are innumerable reports of the formation of atherosclerotic plaques in the aorta and coronary vessels of chickens fed atherogenic diets. Little work has been done, however, on the development of atherosclerosis in the cerebral arteries. A recent review of comparative atherosclerosis<sup>1</sup> reported that spontaneous atherosclerosis was not found in the cerebral arteries of chickens, turkeys, rabbits, baboons and pigeons; whereas it was observed in swine and older dogs. Cerebral atherosclerosis did not develop in rabbits fed cholesterol, unless their cerebral circulation was impaired by ligation of either the carotid artery, the jugular vein or both<sup>2</sup>. Investigation of the cerebral vessels of chickens was of interest because of the paucity of information available, especially as related to birds fed atherogenic diets.

Male and female chickens were fed either an atherogenic or a non-atherogenic diet for 2 years. The composition of the diets has been described previously<sup>3</sup>. The birds were killed and the aorta was removed by dissection from the junction at the heart and its bifurcation into the iliac arteries.

The aorta was divided further into thoracic and abdominal sections and evaluated macroscopically as to severity of atherosclerosis (graded 1-4) and extent of aortic area involved (percentage). The atherosclerotic score was the multiple of these two parameters. Table 1 gives the mean aortic atherosclerotic scores for the birds, and reaffirms the fact that cholesterol-fed chickens develop atherosclerosis (an aortic score of 300 represents a very severe atherosclerotic condition). These birds would have been expected to exhibit coronary atherosclerosis if their hearts had been prepared for examination, because a previous investigation<sup>4</sup> had shown that feeding this atherogenic diet resulted in the development of coronary atherosclerosis. The brains of these birds were removed and prepared as follows. Transverse sections were made through the brain and meninges at three selected sites so that a representative sample of arteries, both small and large, would be transected. The sections were all stained with Verhoeff van Gieson and haematoxylin and eosin and examined "blind". This examination was later repeated, again blind. In both cases the results were identical, and they are shown in Table 1. The lesions were not graded because the majority of arteries were normal, and the few vascular lesions observed were so

Table 1. ATHEROSCLEROTIC SCORE IN THE AORTAE AND CEREBRAL ARTERIES OF CHICKENS FED AN ATHEROGENIC OR NON-ATHEROGENIC DIET FOR 2 YEARS

Females	8	107 $\pm$ 31	363 $\pm$ 20	Trace (1) Normal (7)	9	9 $\pm$ 6	107 $\pm$ 42	Trace (1) Normal (8)

\* Atherosclerotic score  $\pm$  standard error, severity (1-4) times area involved (per cent).

T.A., Thoracic aorta; A.A., abdominal aorta; C.A., cerebral arteries (the lesions were too small to warrant special grading). White Leghorn chickens were used.

small as to warrant no special grading. When present, these lesions could not have given rise to any circulatory disturbance, and they are probably best considered as insignificant.

The results are interesting in that they point out the difference that exists between arterial vessels in the chicken. The cerebral arteries of a chicken fed an atherogenic diet appear to be resistant to the development of atherosclerosis, but the aorta and the coronary arteries, as previously reported, are susceptible to the disease. The reason for this resistance is difficult to explain. In the intimal layer of the cerebral artery, however, there may exist a barrier to the diffusion of cholesterol and other lipids through the arterial wall to the brain. This suggested explanation finds support from the evidence that birds fed an atherogenic diet containing cholesterol did not show an increase in concentration of brain cholesterol, whereas other body tissues showed significant increases in cholesterol level<sup>4,5</sup>. An answer to the question whether the cerebral artery in the chicken does not develop atherosclerosis is as important as whether the aorta and coronary vessels do become atherosclerotic; this information is necessary for a proper understanding of the aetiology of atherosclerosis.

## BIOCHEMISTRY

### Metabolism of Propranolol ('Inderal'\*), a Potent, Specific $\beta$ -Adrenergic Receptor Blocking Agent

THIS is a preliminary report on the metabolism of propranolol<sup>1</sup> (I) in several species, including man.

When propranolol labelled with carbon-14 at C-1 in the naphthalene ring was injected subcutaneously into the rat, mouse, guinea-pig or rabbit at a dose of 1 mg/kg, the majority of the radioactivity was excreted in the urine, mainly during the first 24 h after the injection. In the case of the rat, half the administered radioactivity appeared in the urine during the 24 h immediately after dosing, and only traces of radioactivity were detected in the expired air.

The radioactive metabolites were separated by electrophoresis of the rat urine in 0.05 molar sodium dihydrogen phosphate. There were two main groups, namely, acidic (approximately 30 per cent) and amphoteric (approximately 70 per cent) compounds; only small amounts of basic compounds were found.

A pure acidic metabolite was isolated from the urine of injected rabbits by ion exchange chromatography and

counter-current distribution. It was shown to be identical with a synthetic sample<sup>2</sup> of 2-hydroxy-3-(1'-naphthylthioxy)-propionic acid (II) by melting point and mixed melting point determinations, ultra-violet and infra-red spectroscopy, and thin layer chromatography in two systems.

Two amphoteric compounds were also separated from the urine of injected rats, mice and rabbits by ion exchange and gel filtration chromatography. These compounds were shown to be glucuronides of propranolol (I) and its 4-hydroxy derivative (III). The nature of these was demonstrated by the acidic hydrolysis of the former to propranolol and enzymatic hydrolysis (using  $\beta$ -glucuronidase taken from *Helix pomatia*) of the latter, to a compound shown to be identical with a synthetic sample<sup>3</sup> of 1-(4'-hydroxy-1'-naphthylthioxy)-3-isopropylamino-2-propanol (III) in infra-red and ultra-violet spectroscopy and thin layer and paper chromatography. The two glucuronides were also excreted in the bile of the rat and guinea-pig. Small amounts of propranolol and its 4-hydroxy derivative were detected in the urine of all the species examined.

The same metabolites were obtained after administering propranolol to mice, rats, guinea-pigs, rabbits and man. The main pathways of the metabolism of propranolol are thus demonstrated to be (a) hydroxylation (followed by conjugation with D-glucuronic acid) and (b) side-chain oxidation.

Work on further aspects of this problem including the absorption, distribution, metabolism, excretion and the possible entero-hepatic circulation of propranolol, together with the possibly differing metabolism of its two optical isomers, is in progress and will be reported separately.

I thank Miss E. Renshaw and Mr. P. J. Simons for their expert technical assistance.

### Deaggregation of Chlorophyll *a* by Xanthophylls

It is known<sup>1-3</sup> that the chlorophylls (but not their pheophytins) will aggregate in a variety of non-polar solvents (for example, benzene and carbon tetrachloride), with characteristic spectra for the respective monomers and dimers. These aggregates are concentration-dependent in the usual mass action sense up to a concentration of at least  $10^{-2}$  moles/l. They may be deaggregated by solvents which co-ordinate with the magnesium, for example, alcohols, and the extent of deaggregation may be calculated from the characteristic spectra.

We have found that aggregated solutions of chlorophyll *a* in carbon tetrachloride can be deaggregated by approximately equimolar amounts of leaf xanthophylls, but not by carotenes. The deaggregation shows itself spectroscopically by loss of the shoulder band on the red side of the red absorption band and an increase in intensity of the latter, along with a shift from 668 to 665 nm (Fig. 1). The corresponding spectra for  $\beta$ -carotene show no change over two orders of magnitude of concentration, the strongest having a carotene/chlorophyll ratio of approximately two (Fig. 2).

What is probably an isomerization of neoxanthin to two additional compounds resulted from rechromatography in petroleum ether on a sugar column. Of the three, only the middle compound on the chromatograph could deaggregate. The specificity and sensitivity of the different xanthophylls for deaggregation of both chlorophylls are being investigated.

Without knowing the matrix in which the chlorophylls occur *in vivo*, it might be expected that at the calculated natural concentration (approximately  $10^{-1}$  molar) they may be in a highly aggregated state. Our experiments lead us to presume that xanthophylls in chloroplasts regulate the extent of aggregation of the chlorophylls. The overwhelming concentration of the chlorophylls (for example,  $\sim 115$  chlorophyll *a* + *b*/17 xanthophylls)<sup>4</sup> precludes any but a minor fraction of aggregation control by this class of compounds. Chlorophyll *a* forms at least two different kinds of dimer, however, and it is clear that the accessory components of the chloroplast can regulate the detailed geometry controlling energy transfer in an energy trapping and biochemical function of the chlorophylls.

As a corollary, it should be recognized that difference spectra can result not only from changes in the state of oxidation of a pigment, but also from its state of aggregation or from a conformational change within a particular aggregated state.

This work was performed when one of us (S. A.) was a summer guest in the laboratory of Dr. C. Ponnamperna.

Fig. 1. Deaggregation of chlorophyll *a* by violaxanthin. .... Absorption spectrum of chlorophyll *a* aggregate (I) (dimer) in carbon tetrachloride (1 mg/ml.); ----, I plus violaxanthin (II) in the molecular ratio of approximately 10 : 1; —, I plus violaxanthin (III) in the molecular ratio of approximately 1 : 1. III is approximately identical to the curve for chlorophyll *a* monomer.

Fig. 2. Inability of  $\beta$ -carotene to deaggregate chlorophyll *a* dimers, indicated by lack of increase of absorbance and hypsochromic shift.

### Protein Synthesis by Amoebal Ribosomes

ALTHOUGH some of the first observations localizing the site of protein biosynthesis to microsomes were made with *Tetrahymena*<sup>1</sup>, interest in protozoa has generally been overshadowed by that shown for bacteria, yeast or rat liver, as appropriate cells in which to study the mechanisms of protein synthesis. None the less, the possibilities of variation in the organization of polysomes or in genetic code assignments make these organisms of prime interest. The availability of axenic cultures of *Entamoeba histolytica*<sup>2</sup>, an important pathogen for man (amoebic dysentery and amoebic liver abscess), prompted us to study the polyribosomes of this organism. At present, only the trophozoite can be cultivated axenically.

*E. histolytica* (National Institutes of Health strain 200) were grown at 35° C in a liquid medium consisting of peptones, glucose, serum, a liver digest and vitamin supplement. For the purposes of mass cultivation, 125 ml. Erlenmeyer flasks with screw caps containing 100 ml. medium were used. Yields of  $10-15 \times 10^6$  organisms were collected from each flask at the height of a logarithmic growth phase (96 h) after inoculation of each flask with  $1 \times 10^6$  organisms. Amoebae obtained from twenty growth flasks were chilled and washed twice using Littlefield's medium (0.25 molar *tris* buffer, pH 7.6, 0.005 molar magnesium acetate, and 0.025 molar potassium chloride).

The washed cells were resuspended and broken by 13-14 strokes with a Dounce homogenizer. This process disrupted most of the cells and released intact nuclei. The nuclei and remaining whole cells were sedimented at 2,000*g*, and the homogenization steps repeated. Purified nuclei were obtained from the nuclear pellet by suspending

Fig. 1. Optical density profile of *E. histolytica* ribosomes. A two membered mixing chamber was used to prepare 10–34 per cent sucrose gradients. Two portions of *E. histolytica* ribosomes were treated with RNase at concentrations of 0.1  $\mu\text{g/ml}$  or 10  $\mu\text{g/ml}$  for 10 min at 37°. Polysome profiles were resolved by centrifugation at 25,000 r.p.m. for 2.5 h, using an 'SW 25-1' rotor. Adsorption at 260  $m\mu$  was monitored by passing the gradient, pumped at a rate of 1.0 ml/min, through a Gifford flow cell with a 5 mm light path. —, Control; ---, RNase (0.1  $\mu\text{g/ml}$ ); ·····, RNase (10  $\mu\text{g/ml}$ ).

it in *RSB* (0.01 molar *tris*, pH 7.4, 0.01 molar potassium chloride and 0.003 molar magnesium chloride) and centrifuging this suspension (45 min, 100,000*g*) through successive layers of 0.5 and 2.1 molar sucrose.

The supernatant fluid from the 2,000*g* pellet was clarified by centrifugation at 20,000*g* for 15 min. This solution was centrifuged for 4 h at 105,000*g* to yield a pellet which, when examined by electron microscopy, consisted of glycogen and ribosomal particles (200–300 Å) attached to an endoplasmic reticulum. For the preparation of polyribosomes, sodium deoxycholate was added to the 20,000*g* supernatant fluid to a concentration of 1.2 per cent. This solution was placed over layers of 0.5 and 2.1 molar sucrose and centrifuged for 4 h at 105,000*g* at 2° C. The microsomal or ribosomal pellets were suspended in *RSB* to give a final concentration of 1.5–2 mg ribosomal protein/ml. The Lowry method for determining protein was used<sup>3</sup>.

After passing the post-microsomal supernatant fluid through 0.22  $\mu$  'Millipore' filters, an enzyme fraction was prepared by lowering the pH to 5.0 with 0.1 molar acetic acid. The resultant precipitate was sedimented at 20,000*g* for 20 min and washed twice with water previously distilled over glass. Medium A was added to adjust the protein concentration to 10–12 mg/ml. All samples were stored at –170° C in liquid nitrogen.

Table 1 shows the activities of three fractions in promoting the incorporation of an amino-acid labelled with carbon-14 into a product precipitable with acid. The assay system made use of the filter paper technique of Mans and Novelli<sup>4</sup>: 100  $\mu\text{l}$ . samples were removed from the incubation mixtures at 5 min, 10 min and 20 min and pipetted on to 2.3 cm disks of Whatman No. 3 filter paper. The disks were washed in 5 per cent trichloroacetic acid (TCA) and 0.25 per cent sodium tungstate at 4° C. After washing for 45 min, the disks were heated to 90° C for 7 min in fresh 5 per cent TCA. They were then washed in cold 5 per cent TCA, twice in ethanol, dried, and counted in a liquid scintillation spectrometer. The activity of the ribosomal preparation was equal to

Table 1. POLY U STIMULATION OF CARBON-14-PHENYLALANINE INCORPORATION

		Specific activity		Ratio (to ribosomes)
		c.p.m.	m $\mu\text{moles}$

3	Ribosomal fraction	$1.57 \times 10^4$	0.20	1.0

The reaction mixture contained in a total volume of 0.5 ml.: 130  $\mu\text{moles}$  of sucrose, 20  $\mu\text{moles}$  of *tris* buffer pH 7.6, 20  $\mu\text{moles}$  of ammonium chloride, 28  $\mu\text{moles}$  of potassium chloride, 4.7  $\mu\text{moles}$  of magnesium acetate, 2.4  $\mu\text{moles}$  of  $\beta$ -mercaptoethanol, 0.48  $\mu\text{mole}$  of ATP, 0.12  $\mu\text{mole}$  GTP, 2.5  $\mu\text{moles}$  of phosphoenolpyruvate, 28  $\mu\text{g}$  of phosphoenolpyruvate kinase, 100  $\mu\text{g}$  of Poly U, 1  $\mu\text{c}$ . of carbon-14-labelled phenylalanine 1.0 mg of pH 5 enzyme protein and 0.25 mg of ribosomal (or nuclear) protein. Specific activities are expressed as c.p.m. or m $\mu\text{moles}$  of carbon-14-labelled phenylalanine incorporated into acid precipitable phenylalanine/mg of ribosomal (or nuclear) protein/60 min.

that previously observed with rat liver, when either cytoplasmic or nuclear ribosomes were used<sup>5</sup>.

*E. histolytica* ribosomes were fractionated on 10–34 per cent sucrose gradients (Fig. 1) and sedimentation values calculated with the *L* cell monomeric ribosome ( $\sim 74S$ ) as a marker, using the procedure of Martin and Ames<sup>6</sup>. The protozoan monomer migrated the same distance in the density gradient as the corresponding mammalian particle. Two additional peaks, representing a dimer and trimer, were also observed. When plotted as log *S* against log number of apparent monomers, a slope was obtained similar to that obtained by Pfuderer *et al.*<sup>7</sup> with liver polysomes. There was a shift to the monomer and dimer region with the addition of as little as 0.1  $\mu\text{g/ml}$ . RNase. Ribonucleoprotein particles with sedimentation properties similar to the monomer and dimer have been recorded by Scherbaum<sup>8</sup> in *Tetrahymena pyriformis*. An optical density peak, lighter than the monomeric ribosome, was found at concentrations of magnesium ions (3 mmoles/l.) which would normally suppress the disruption of monomers into their sub-units. This component may correspond to the 40S sub-unit reported in normal HeLa cells at lower concentrations of magnesium by Girard *et al.*<sup>9</sup>, or in HeLa cells infected with vaccinia at normal concentrations of magnesium by Joklik and Becker (personal communication). In the HeLa cell, the particle may represent a ribosomal precursor to which template RNA attaches before forming a polysome.

*E. histolytica* ribosomes were examined for a capacity to promote the incorporation of labelled amino-acids under a variety of conditions. The slope of the initial incorporation velocity  $V_0$  varied with the ribosomal concentration at a constant enzyme concentration (Fig. 2). Corresponding trials with synthetic polynucleotides indicated that 100  $\mu\text{g}$  of polynucleotide/reaction mixture achieved the optimal activity. When stimulated by polyuridine (Poly U), polyphenylalanine synthesis was

Fig. 2. Dependence of the rate of amino-acid incorporation on ribosome concentration.  $V_0$  is calculated from the initial reaction rate expressed as m $\mu\text{moles}$  of acid precipitable phenylalanine/60 min.

5	" + DNase (30 μg/ml.)	$1.57 \times 10^5$	0.20	-
6	" + Puromycin (10 μmole/ml.)	$0.393 \times 10^5$	0.05	76
7	" + Tetracycline (25 μmole/ml.)	$0.55 \times 10^5$	0.07	65

The assay conditions are similar to those of Table 1 except that a single component was removed from, or added to, the reaction tube at zero time. Specific activity is expressed as mμmoles or c.p.m. of acid precipitable phenylalanine/mg ribosomal protein/60 min.

enhanced by a factor of from twelve to fifteen and increased linearly for 25 min. When three homopolymers (Poly U, Poly A and Poly C) were examined for their capacity to encode their corresponding amino-acids according to the assignments of Brimacombe *et al.*<sup>10</sup>, an enhanced formation of polypeptide was noted in the predicted direction.

Table 2 indicates the amount of product when a single component was removed from, or added to, the reaction mixture at the beginning of the experiment. The formation of the product depended on enzyme catalysis and the presence of ribosomes. Tetracycline, an antibiotic to which the mammalian protein synthesizing mechanism has appeared refractory, depressed polypeptide formation in this system at a low concentration. The *in vivo* activity of this drug in amoebiasis is well established. Recently, Suarez and Nathans<sup>11</sup> have shown that this antibiotic inhibits bacterial protein synthesis by competitively blocking one of the amino-acyl tRNA binding sites on the 50S ribosomal sub-unit. Although the drug might decrease nutrients available to non-axenic amoeba through a reduction of bacterial polypeptides, these results suggest that tetracycline may have a direct action on this protozoan.

### Ribosome and Polyribosome Disappearance during *in vivo* Erythroid Maturation

THE maturation of the mammalian erythroid cell is marked by loss of the ability to synthesize protein<sup>1</sup>. The predominant site of protein synthesis within the cell is the polyribosome, an aggregate of two or more single ribosomes<sup>2</sup>. Although the decline in protein synthesis which accompanies erythroid maturation is apparently related both to a reduction in the cell content of polyribosomes and

to a decrease in their functional capacity<sup>3-5</sup>, there has been disagreement over the rates of polyribosome and single ribosome disappearance. It has been claimed, on the basis of *in vitro*<sup>3</sup> and *in vivo*<sup>5,6</sup> investigations, that erythroid maturation is accompanied by a selective loss of heavier polyribosomes, which results in an increasing proportion of smaller aggregates and single ribosomes as the reticulocyte ages. Other investigations have shown that there is a relatively constant proportion of polyribosomes in reticulocytes of different ages<sup>4,7</sup>. We have developed a system which allows longitudinal investigation of a population of reticulocytes as they mature *in vivo*, unaffected by continued production of new erythroid cells. Investigations of ribosome behaviour in this system indicate that with maturation all classes of ribosomes disappear at proportional rates, and that in particular there is no orderly shift of polyribosomes from larger to smaller aggregates.

The RNA of the newly formed rabbit reticulocytes induced by subcutaneous administration of phenylhydrazine was labelled by intravenous administration of 5-10 mc. of phosphorus-32 at the time of the final phenylhydrazine injection and 40 h before collection of the cells. The haemoglobin of the reticulocytes was labelled with iron-59 administered intravenously, given 24 h before cell collection. Donor cells, consisting of more than 80 per cent reticulocytes, were washed and infused into a recipient rabbit pretreated for 2 days with a daily intravenous dose of 1 mg of colchicine in order to suppress autogenous red cell production. Daily colchicine administration continued for the duration of the experiments. At intervals up to 72 h, blood samples were obtained from the recipient to determine the fate of the infused reticulocytes and their content of RNA and ribosomes. Reticulocytes were enumerated by supravital staining with new methylene blue dye. Ribosomes were recovered from stroma-free haemolysates by sedimentation at 150,000g and characterized by their sedimentation properties in sucrose density gradients<sup>2</sup>. Radioactivity incorporated into the ribosomes was determined by techniques described in detail elsewhere<sup>2</sup>, and that of haemoglobin in a well-type scintillation detector.

The sequence of events which follows infusion of the donor cells into the recipient animal is shown in Fig. 1. Within 15 min the circulating reticulocytes in the recipient had increased to 38 per cent from the colchicine-suppressed level of 2 per cent, and then progressively decreased to 4 per cent over the next 20 h. That the decrease in circulating reticulocytes was morphological evidence of maturation, and not of cell sequestration and destruction, is indicated by failure of the specific radioactivity of circu-

Fig. 1. Reticulocytosis and specific activity of <sup>59</sup>Fe-labelled haemoglobin in the recipient animal following infusion of donor reticulocytes. In this experiment the recipient blood volume calculated by dilution of <sup>59</sup>Fe was 331 ml. and by dilution of infused reticulocytes, 309 ml. (●, specific activity of haemoglobin; ○, reticulocytosis).

lating haemoglobin in the recipient to decline. The slight rise in the specific activity of haemoglobin was consistently noted and is probably caused by senescent loss of the recipient's unlabelled cells. Previous infusion investigations with phenylhydrazine-induced reticulocytes have indicated a dual population of cells, with as many as 55 per cent of the cells rapidly removed from circulation<sup>8</sup>. This problem was avoided by timing the collection of blood so that less than 5 per cent of the donor cells contained Heinz bodies.

The ribosome content of the infused cells progressively decreased with maturation (Fig. 2). The specific activity of the <sup>32</sup>P-labelled ribosomes was constant, indicating no significant delivery of unlabelled new reticulocytes to the peripheral blood during this time. The average life span of the infused cell population as reticulocytes, on the basis of ribosome content (Table 1), varied between 11 and 15 h in the five animals investigated.

\* Determined as described for Fig. 2.

† Determined by incorporation of phosphorus-32 into ribosomes sedimenting in appropriate zones of a sucrose density gradient under the conditions described for Fig. 3.

The behaviour of the various classes of ribosomes during *in vivo* maturation was examined by analysis of sucrose density gradient patterns of isolated ribosomes. The polyribosome content of maturing reticulocytes in three experiments is shown in Table 1. The proportion of ribosomes existing as single ribosomes and as aggregates of 2, 3, 4 and 5 or more ribosomes was determined by the proportion of phosphorus-32 incorporated into appropriate

Fig. 2. <sup>32</sup>P-labelled ribosome content and specific activity of peripheral blood in the recipient following infusion of donor reticulocytes. Ribosomes were isolated from stroma-free lysates of red cells by centrifugation at 150,000g for 2 h. Milligrams of ribosomes recovered were calculated assuming a coefficient of extinction of 11 O.D. units/mg at 260 mμ. Disappearance of ribosomes based on c.p.m. of incorporated phosphorus-32 gave a curve identical to that of optical density measurements. (○, ribosome content of cells; ●, ribosome specific activity).

Fig. 3. Sucrose density gradient patterns of <sup>32</sup>P-labelled ribosomes following infusion of donor reticulocytes into the recipient. Ribosomes were recovered from stroma-free cell lysates at the times indicated and equal amounts sedimented in a 'Spinco SW-25-3' rotor through a linear gradient of 5–20 per cent of sucrose in 1.5 × 10<sup>-3</sup> magnesium chloride, 1 × 10<sup>-3</sup> molar *tris*, pH 7.5, for 2.5 h at 25,000 r.p.m. at 4° C. Fractions for determination of radioactivity were collected after the distribution of ribosomes in the gradient had been determined by absorbance at 260 mμ in a 'Gilford model 2000' recording spectrophotometer.

regions of the gradients. In experiment 1, aggregates of more than three ribosomes could not be adequately resolved. Examples of gradient patterns, obtained at 15 min, 1 h and 5 h in one of the experiments, are shown in Fig. 3. During the period of observation, when reticulocytosis decreased from 15 to 8 per cent and ribosome content fell from 0.17 to 0.09 mg/ml. of packed cells, the size distribution of the ribosomes remained constant. The results show that as a population of reticulocytes matures *in vivo* all classes of ribosomes disappear at proportional rates.

Previous analyses of the biochemical events which occur during erythroid maturation have utilized separation of cells on the basis of density, which is related to cell age, and longitudinal investigations during *in vitro* incubation. Rowley<sup>5</sup> and Glowacki and Millette<sup>4</sup> separated reticulocytes of various ages on albumin density gradients and arrived at opposite conclusions concerning ribosome disappearance. Rowley, in agreement with investigations of reticulocyte maturation *in vitro*<sup>3</sup>, concluded that maturation was accompanied by a preferential loss of polyribosomes. Glowacki and Millette<sup>4</sup> found no decrease in polyribosome proportion in progressively more mature reticulocytes. The proportion of monosomes in the very oldest cells appeared slightly increased, but there was no change in the size distribution of the remaining polyribosomes. Danon and his co-workers<sup>6</sup> investigated maturing reticulocytes *in vivo* in animals which had been treated with actinomycin in order to suppress continued erythroid production. His results, showing an orderly loss of larger polyribosomes with maturation, may be explained by the known impairment of energy metabolism by actinomycin<sup>9</sup>. It has been shown that other agents which interfere with energy utilization cause a reversible orderly disaggregation of polyribosomes in the intact cell<sup>10</sup>.

Our investigations meet two essential requirements for investigating aspects of erythroid maturation. These requirements are that the investigation should be done under physiological conditions and that maturation should occur without continued input of new cells. The data show conclusively that during erythroid maturation in the intact animal all classes of ribosomes disappear at proportional rates. Although the population of reticulocytes which we observed was heterogeneous with respect to age, this does not invalidate the findings because the cells were progressively maturing without continued delivery of younger cells. The absence of an orderly and progressive breakdown of polyribosomes during erythroid maturation

under physiological conditions is consistent with electron micrograph evidence of the presence of polyribosomes in cells containing very few ribosomes<sup>8</sup>. These findings are not necessarily in disagreement with *in vitro* investigations<sup>9</sup> where examinations were limited to initial and very late stages of maturation. Our data do not rule out a selective breakdown of polyribosomes which might occur as a terminal event in the life span of the reticulocyte.

This investigation was supported by grants from the U.S. Public Health Service, the Cardeza Foundation for Hematologic Research, and the Smith, Kline and French Foundation. We thank Mrs. Maria Nakazawa and Miss Stephanie Mendlow for technical assistance.

### Glyoxylate as a Substrate for Lactate Dehydrogenase

If 2-oxobutyrates are substituted for pyruvate as substrate for lactate dehydrogenase (LD), it is found to be more readily reduced by the electrophoretically faster moving LD isoenzymes than by the slower moving LD isoenzymes<sup>1,2</sup>. Because glyoxylate may also serve as a substrate for LD (ref. 3), we investigated the effect of LD isoenzyme fractions on this compound and compared the findings with those obtained with pyruvate and 2-oxobutyrates.

Crystalline suspensions of the electrophoretically fastest migrating (LD1 from pig heart) and slowest migrating (LD5 from rabbit muscle) LD isoenzymes were appropriately diluted with distilled water just before use. The substrates glyoxylate and 2-oxobutyrates were prepared as 1.0 molar and 0.1 molar solutions, respectively, in 0.067 molar Sørensen phosphate buffer (pH 7.4) after previous neutralization with saturated potassium hydroxide solution. Portions of equal volume were stored at -18° C until required. Sodium pyruvate was used freshly dissolved in phosphate buffer.

Enzyme activities were determined with a reaction mixture containing 2.7 ml. of 0.067 molar Sørensen phosphate buffer pH 7.4: 0.1 ml. of reduced nicotinamide-adenine dinucleotide (NADH<sub>2</sub>) freshly prepared at a concentration of 2.5 mg NADH<sub>2</sub>/ml. phosphate buffer and 0.1 ml. of enzyme preparation. After a suitable period of equilibration the reaction was started by the addition of 0.1 ml. of substrate solution, and enzyme activities determined by measuring the rate of decrease in optical density at 340 mμ and 25° C.

Inhibitor studies were also carried out with oxamate (0.02–0.5 mmoles/l.) or oxalate (0.01–0.2 mmoles/l.) incorporated into the reaction mixture immediately before the substrate solution was added. For investigations

of the inhibition by urea, enzyme and inhibitor were incubated in the reaction mixture for 15 min at 25° C before the substrate was added.

The concentration of glyoxylate required for maximal LD5 activity (33 mmoles/l.) was found to be considerably higher than that required for maximal activity of LD1 (6.67 mmoles/l.). High concentrations of glyoxylate had an inhibitory effect, which was most marked with LD1. In both these respects glyoxylate behaved similarly to pyruvate and to 2-oxobutyrates; however, the apparent enzyme substrate constants (*K<sub>s</sub>*) for LD1 and LD5 were much higher with glyoxylate as substrate (about  $5 \times 10^{-3}$  moles/l. for LD1 and  $30 \times 10^{-3}$  moles/l. for LD5) than the corresponding values with pyruvate or 2-oxobutyrates<sup>2</sup>.

Comparison was made between the activities of LD1 and LD5 using 0.7 mmolar pyruvate<sup>4</sup> and either 3.3 mmolar 2-oxobutyrates<sup>1</sup> or 6.67 mmolar glyoxylate (final concentration). Differentiation between the two isoenzymes, using glyoxylate, was less than that obtained with 2-oxobutyrates as substrate (Table 1).

Table 1. ACTIVITIES OF LD1 AND LD5 WITH 2-OXOBUTYRATE AND GLYOXYLATE RELATIVE TO THEIR ACTIVITIES WITH PYRUVATE

Isoenzyme	Activity ratios	
	2-Oxobutyrates/pyruvate	Glyoxylate/pyruvate
LD1	1.03	0.81
LD5	0.23	0.41

Inhibitor studies confirmed that oxamate acts as a competitive inhibitor for LD with both pyruvate and 2-oxobutyrates; the inhibition was more marked with LD1 than LD5 (refs. 5 and 6). With glyoxylate the inhibition was again found to be competitive in type and more marked with LD1. Oxamate inhibition with glyoxylate was similar in degree to that observed with 2-oxobutyrates but greater than that seen with pyruvate.

Oxalate, which is known to act as a non-competitive inhibitor with pyruvate and 2-oxobutyrates<sup>4,6</sup>, was also a non-competitive inhibitor with glyoxylate. A similar degree of inhibition was seen with all three substrates, and was more marked with LD1 than with LD5.

Urea inhibition of the LD isoenzymes with glyoxylate as substrate was similar to that found with pyruvate and 2-oxobutyrates in being more marked with LD5 and LD1 (refs. 7 and 8). When the ratios of enzyme activities with and without inhibitors were plotted against the concentration of urea, the curves obtained were of similar shape, showing marked inflexions. With glyoxylate inflexions occurred at about 1.0 molar urea for LD5 and about 2.0 molar for LD1. The inflexions with 2-oxobutyrates and pyruvate occurred at a similar urea concentration.

Despite their difference in structure both glyoxylate and 2-oxobutyrates have been shown to behave with remarkable similarity towards the LD isoenzymes. The type of inhibition of the LD isoenzymes was similar with all three substrates, and the degree of inhibition similar with glyoxylate and 2-oxobutyrates. Both glyoxylate and 2-oxobutyrates showed greater activity with LD1 than with LD5, although 2-oxobutyrates was a superior differential substrate in this respect. It is not anticipated, therefore, that glyoxylate as a substrate for LD will prove of clinical value in the way that 2-oxobutyrates as a substrate for LD ("alpha-hydroxybutyrate dehydrogenase") has found diagnostic application in cardiac disorders<sup>9,10</sup>.

Observations with LDX, the isoenzyme derived from human spermatozoa, have shown that this isoenzyme more readily reduces 2-oxobutyrates than would be anticipated from its electrophoretic mobility<sup>11</sup>. Preliminary investigations have shown similar findings with glyoxylate, which emphasizes the similarity between glyoxylate and 2-oxobutyrates as substrates for LD despite their dissimilar structures. This finding serves as evidence against a suggested specific metabolic role for 2-oxobutyrates in the metabolism of spermatozoa<sup>11</sup>.

### Stimulation of Insulin Secretion by Theophylline

RECENT reports that epinephrine and glucagon, hormones which affect the generation of cyclic 3',5'-AMP, also influence the release of pancreatic insulin<sup>1-5</sup> have led us to examine the effect of this cyclic nucleotide on insulin secretion. In the present experiments the effects on insulin secretion of theophylline, a methyl xanthine derivative which inhibits cyclic nucleotide phosphodiesterase<sup>6</sup> and increases the intracellular steady state level of cyclic 3',5'-AMP, alone and in combination with epinephrine and alpha and beta adrenergic blocking agents, have been examined in the rat.

Male Charles River rats, weighing 200-400 g and fasted for 24-48 h, were adrenalectomized under ether anaesthesia 3 h before use to exclude acute variations in catecholamine secretion during the experimental procedure. Under pentobarbitone anaesthesia (3 mg/100 g intraperitoneally), a polyethylene catheter was inserted through the jugular vein into the right atrium for theophylline injection (15 mg in 0.5 ml. saline) and blood sampling. Two control blood samples were obtained before injecting theophylline. 0.4 ml. blood samples were afterwards withdrawn at frequent intervals, centrifuged and portions of plasma taken for insulin radioimmunoassay<sup>7</sup> and glucose determination<sup>8</sup>. Rat plasma insulin levels are given in terms of porcine insulin equivalents. The rates of disappearance of plasma insulin were deter-

mined using porcine insulin labelled with iodine-125 (ref. 9).

In the acutely adrenalectomized rat fasted for 48 h, theophylline produced a prompt rise in plasma insulin which could be detected within 1 min (Fig. 1). Plasma insulin concentrations up to ten times as high as the basal values were reached 5-10 min after injection and remained elevated for 20-30 min. The plasma insulin response following theophylline is not a consequence of the associated slight rise in blood sugar because (a) raising blood sugar to even greater levels by glucose infusion elicited only a minimal insulin response (Fig. 1) and (b) the increase in plasma insulin induced by theophylline persisted even after the blood sugar had returned to control concentrations.

We have used the area circumscribed by the plasma insulin response curve, expressed in  $\mu\text{U}\cdot\text{min}$ , as an index of insulin secretion. Although this expression is not a precise measure of pancreatic secretion rates, it is a valid technique for comparing insulin secretion under varying conditions provided the rate of insulin degradation remains unchanged. The half-life of plasma insulin did not differ significantly between control animals ( $33 \pm 4.4$  min) and rats treated with theophylline ( $32 \pm 2.8$  min). Insulin secretion stimulated by theophylline ( $487 \pm 42 \mu\text{U}\cdot\text{min}$ ) was more than three times that seen after glucose infusion ( $148 \pm 26 \mu\text{U}\cdot\text{min}$ ). When insulin secretion is expressed in terms of the rise in blood glucose during the 30 min experimental period, the insulin/glucose ratio is  $16.2 \mu\text{U}/\text{mg}$  glucose after theophylline and  $0.24 \mu\text{U}/\text{mg}$  glucose after infusion of glucose, indicating that the insulin response induced by theophylline is sixty-nine times greater than that expected from the rise in plasma glucose.

Within 1 min of the injection of theophylline, portal vein insulin increased from  $136 \pm 16$  to  $328 \pm 28 \mu\text{U}/\text{ml}$ . (Fig. 2). This prompt response followed by a subsequent fall and more prolonged increase in plasma insulin is consistent with an immediate effect of an initial bolus of theophylline which then underwent uniform mixing in the plasma compartment.

Recent studies by Porte<sup>11</sup> suggest that alpha adrenergic receptors mediate the inhibitory effect of epinephrine on insulin secretion, whereas beta adrenergic receptor

Fig. 2. Effect of theophylline on the plasma insulin levels of portal and right atrial venous blood in 15 h fasted, adrenalectomized rats. Theophylline was given intravenously in a single injection of 15 mg in 0.5 ml. physiological saline. Each point represents the mean  $\pm$  S.E.M. of five rats.

Fig. 1. Effect of infusion of theophylline and intravenous glucose on plasma insulin responses of 48 h fasted, adrenalectomized rats. Theophylline was given intravenously in a single injection of 15 mg in 0.5 ml. physiological saline. Glucose was infused at a rate of 3 mg/min/100 g body weight for 10 min. Each point represents the mean  $\pm$  S.E.M. of four to eight rats.

stimulation increases release of the insulin. Theophylline, injected 10 min after the beginning of an epinephrine infusion ( $0.1 \mu\text{g}/\text{min}/\text{kg}$ ), provoked a prompt 800 per cent rise in plasma insulin. In the presence of alpha adrenergic blockade and epinephrine infusion, theophylline provoked an extraordinary increase in plasma insulin content ( $3,000\text{--}4,000$  per cent rise to  $348 \pm 15 \mu\text{U}/\text{ml.}$ ) which continued throughout the experimental period and resulted in a rapid fall in plasma glucose (Fig. 3). During epinephrine infusion and beta adrenergic receptor blockade, theophylline injection produced no detectable plasma insulin response. These results suggest that alpha and beta adrenergic receptors in the islet beta cells mediate divergent effects of epinephrine on cyclic  $3',5'$ -AMP synthesis; alpha receptor inhibiting and beta receptor increasing the generation of cyclic nucleotide. Specific studies of alpha receptor stimulation on cyclic AMP generation have not been reported, but Murad *et al.*<sup>12</sup> have shown that beta receptor blockade prevented epinephrine stimulation of adrenyl cyclase activity in the dog heart.

Fig. 3. The effect of theophylline on the plasma insulin responses of 48 h fasted, acutely adrenalectomized rats during an epinephrine infusion with and without alpha and beta adrenergic receptor inhibition. Epinephrine was infused at the rate of  $0.1 \mu\text{g}/\text{min}/\text{kg}$  body weight. Alpha receptor blockade was established with phentolamine ( $10 \text{ mg}/\text{kg}$  intraperitoneally) and beta receptor blockade with propranolol ( $1 \text{ mg}/\text{kg}$  given intravenously) given immediately before starting the epinephrine infusion. Theophylline,  $15 \text{ mg}$  in  $0.5 \text{ ml.}$  of physiological saline, was injected intravenously 10 min after beginning the epinephrine infusion. Each point represents the mean  $\pm$  S.E.M. of five rats. —, Control; ---, phentolamine; ···, propranolol.

Cyclic  $3',5'$ -AMP is involved in a wide variety of apparently divergent processes ranging from activation of enzymes such as phosphorylase<sup>13</sup>, UDPG glucogen alpha-4-glucosyltransferase<sup>13</sup> and tryptophan pyrrolase<sup>14</sup> to increasing adipose tissue lipolysis<sup>15,16</sup>, steroid hydroxylation<sup>17</sup>, uterine protein synthesis<sup>18,19</sup> and permeability of the toad bladder to water<sup>20</sup>. The results of this experiment indicate still another function for this nucleotide; namely, activation of a system involved in insulin secretion. The possibility that this effect may be of a more generalized nature in that the cyclic nucleotide participates in the secretory mechanisms of other peptide hormones merits further investigation.

### Photo-induced Benzyl Substitution of Flavins by Phenylacetate: a Possible Model for Flavoprotein Catalysis

PHOTOREDUCTION of flavins is known to occur with amino-acids<sup>1,2</sup> or, intramolecularly, with the ribityl side chain of the flavin<sup>3,4</sup> as hydrogen donors. We wish to report here a new photochemical reaction of flavins which could also explain the mechanism of flavin and flavoenzyme catalysis as a whole.

We have found that, under anaerobic conditions, flavoquinones of general type I (scheme I) are rapidly and irreversibly bleached by visible light in the presence of phenylacetate anions. During this reaction a quantity of carbon dioxide stoichiometric with the flavin reduced is liberated, as measured manometrically. At higher concentrations of flavin and with suitable flavoquinone models, for example, 3-methylumiflavin (I,  $R_1 = R_2 = \text{CH}_3$ ), the photoreduced product precipitates quantitatively from aqueous reaction mixture and can be filtered off in the presence of traces of  $\text{S}_2\text{O}_4^{2-}$  as anti-oxidant. The product contains the benzyl residue of the phenylacetate in an apparently covalent bond to the flavin nucleus. Analysis established the product as a mixture of isomeric flavohydroquinones IIa and IIb, separable by their different solubility in dilute aqueous ammonia: IIa (melting point,  $225^\circ\text{--}230^\circ\text{C}$ ;  $\lambda_{\text{max}}$ ,  $342 \text{ m}\mu$  at pH 5) undergoes salt formation in this medium and is reprecipitated by acetic acid, preferably in the presence of  $\text{S}_2\text{O}_4^{2-}$ . The ammonia insoluble IIb (decomposition temperature,  $230^\circ\text{C}$ ;  $\lambda_{\text{max}}$ ,  $364 \text{ m}\mu$  at pH 5) can be purified by recrystallization from non-polar solvents. When the temperature of photoreaction is increased to  $50^\circ\text{C}$ , IIb is obtained exclusively, in a yield of 95 per cent.

Both compounds are stable in the dry, crystalline state and were shown by elementary analysis to be structural isomers  $\text{C}_{21}\text{H}_{22}\text{O}_2\text{N}_4$  (for I,  $R_1 = R_2 = \text{CH}_3$ ).

The formation of both compounds IIa and IIb is not rapidly reversible by air, as is the case for unsubstituted

flavohydroquinones. Instead, compound IIa reacts relatively slowly with air, whereby an olive green intermediate is formed which by electron spin resonance spectrometry was found to be a radical species. Its yield was found by double integration to reach 50 per cent and more of total flavin present. The radical disappeared only after several hours of aeration, to yield a third leucoflavin (IIc) which, unlike IIa or IIb, appeared to be stable towards oxygen even in the light. When the reaction  $\text{IIa} \rightarrow \text{IIc}$  was conducted by iodine instead of oxygen, the consumption of exactly two electron equivalents was measured. IIb, on the other hand, was found to be easily photo-oxidized, rendering I in a yield of 100 per cent. In the absence of light it was stable towards oxygen and in the absence of oxygen it was stable towards light. Formation of an intermediate radical was not observed. When the photo-oxidation was carried out with iodine instead of oxygen the consumption of 2.0 equivalents of iodine was measured. IIc, in turn, could be quantitatively reconverted to I by acid and to IIa by reduction with  $\text{S}_2\text{O}_4^{2-}$ .

The structure of the products IIa-c was established by combined spectrometry, ultra-violet, infra-red, nuclear magnetic resonance and electron spin resonance, acidimetry, and by comparison with known flavin derivatives. Scheme 1 (shown in Fig. 1) for flavin photoreduction and reoxidation was derived. The following evidence is given for the structures shown in Fig. 1. IIa shows the acidic NH characteristic for leucoflavins<sup>6</sup>, for example, FMNH<sub>2</sub>, with a  $pK_a$  of 7.2. The radical, which is green in the neutral (see here), and red in the protonated state, gives a complex electron spin resonance hyperfine pattern (unpublished work of Palmer, Massey and Hemmerich) unaffected by  $\text{H}_2\text{O}/\text{D}_2\text{O}$ -exchange, indicating lack of proton substituent at N(5) (refs. 6 and 7). The hyperfine pattern, however, reflects the deuteration of the benzyl residue, that is, replacement of  $\text{C}_6\text{H}_5\text{CH}_2\text{COO}^-$  by  $\text{C}_6\text{H}_5\text{CD}_2\text{COO}^-$  in the photoreduction, which indicates hyperconjugation between benzylmethylene and a position of high spin density in the heteroaromatic nucleus<sup>6,7</sup>.

The red radical cation from IIa has the same electron spin resonance hyperfine pattern as known 5-benzyl-leucoflavins<sup>6</sup> and the position of its absorption band at 510 m $\mu$  is characteristic of 5-alkylation<sup>8</sup>, compared with the  $\lambda_{\text{max}}$  of 490 m $\mu$  of 5-unsubstituted analogues<sup>6</sup>. IIa itself exhibits all CH-groups of the flavoquinone (I) in nuclear magnetic resonance, and in addition five unresolved phenyl-CH plus a benzyl  $\text{CH}_2$  at 4.35 p.p.m. ( $\text{CDCl}_3$ ). The latter signal is reduced by about 90 per cent in size in the phenyl-deuteroacetate photo-product.

IIb shows no  $pK_a$  and the same nuclear magnetic resonance signals, except that  $\text{CH}_2$  appears at 3.0 p.p.m. ( $\text{CDCl}_3$ ) as an AB-system. This clearly shows that the benzyl residue is fixed to an asymmetric carbon atom. The two methylene protons are therefore not equivalent. Again the  $\text{C}_6\text{H}_5\text{CD}_2$ -analogue is deficient in this signal. The free N(5)H is also seen in the nuclear magnetic resonance of IIb at 4.7 p.p.m. ( $\text{CDCl}_3$ ) and is exchangeable by  $\text{D}_2\text{O}$  as is to be expected.

IIa shows two strong CO bands at 1,700 and 1,640  $\text{cm}^{-1}$  in the infra-red ( $\text{CH}_2\text{Cl}_2$ ) and a very broad amide NH-stretching in the 3  $\mu$  region, whereas IIb shows only one strong CO band at 1,670  $\text{cm}^{-1}$  ( $\text{CH}_2\text{Cl}_2$ ), a weaker one at 1,725  $\text{cm}^{-1}$ , and the very sharp pyrrole type NH at 3,350  $\text{cm}^{-1}$ .

IIc, finally,  $\text{C}_{21}\text{H}_{22}\text{O}_3\text{N}_4$  after elementary analysis, displays in the near ultra-violet two peaks at 308 and 356  $\mu$  in methyl alcohol. In the infra-red, it shows a strong CO band at 1,640  $\text{cm}^{-1}$  and a weaker one at 1,725  $\text{cm}^{-1}$ , but no pyrrole-NH. The proton nuclear magnetic resonance spectrum shows all protons of IIa, but the two C- $\text{CH}_3$  groups now have distinctly different chemical shifts, indicating chemical non-equivalence, and therefore higher asymmetry of  $\pi$ -electron distribution, compared with IIa. The benzyl- $\text{CH}_2$  protons are now found at 4.65 p.p.m. ( $\text{CDCl}_3$ ) and a new broad signal caused by one  $\text{D}_2\text{O}$ -exchangeable proton is found at 1.65 p.p.m. ( $\text{CDCl}_3$ ). Thus, the structure of IIC appears to be that of a pseudo base derived from a 5-alkyl flavoquinone quaternary salt. In agreement with this, IIC is converted at  $\text{pH} < 2$  to a purple coloured compound ( $\lambda_{\text{max}}$ , 580 m $\mu$ ) which decomposes within minutes to give free flavoquinone (I) or, in the absence of oxygen, free flavosemiquinone cation.

Photoreduction of flavins was found with the following substrates: phenylacetic acid, mandelic acid, phenylpropionic acid, phenylglycine, indolyl-3-acetic acid, naphthylacetic acid. Photodecarboxylation of phenylacetate was found with the following flavins: FAD, FMN, riboflavin, lumiflavin, isoriboflavin, as well as various kinds of 2,3,4-substituted flavins, alloxazines and pteridines.

The reaction described here, in addition to the recently described reaction of glucose oxidase<sup>9</sup> and other flavo-proteins with bisulphite, suggests that the chemical reactivity of N(5) may be of importance in flavoprotein catalysis. Recent years have seen the report of the flavoprotein nature of several enzymes which possess no known redox function (oxynitrilase<sup>10</sup>, glyoxylate carboligase<sup>11</sup>). Thus the flavin coenzymes may serve a dual function in enzyme reactions; in addition to their well known redox properties they may catalyse reactions through chemical substitution reactions. Indeed, it is even possible that the redox function may result by group transfer rather than electron or H-transfer. It is remarkable that flavoproteins in general act only on compounds containing CH-bonds which are "activated" by substituents with large +M effects, such as DPNH, thioesters (acyl coenzyme A), amino-acids and aldehydes. No simple alcohol oxidation reaction catalysed by flavo-proteins is known; in the known cases where flavins are involved in oxidation of alcoholic groups (for example, glycolic acid oxidase,  $\alpha$ -hydroxyacid oxidases) the CH-bond is also "activated" by the carboxyl substituent,

Fig. 1. Scheme 1 for photoreduction and reoxidation of flavin.

### Synthesis of Serotonin by Pineal Glands of the Rat in Organ Culture

THE pineal gland of the rat has been shown to contain large quantities of the indole serotonin<sup>1</sup>. This organ can also metabolize serotonin by a unique pathway to form the hormone melatonin (5-methoxy *N*-acetyltryptamine)<sup>2</sup>. The content of serotonin<sup>1,3</sup> and the activity of the melatonin-forming enzyme<sup>4</sup> in the pineal have been found to vary with a 24 h cycle. These rhythms are controlled by information transmitted to the pineal through its sympathetic nerves<sup>5</sup>.

Little is known about the biochemical control of serotonin synthesis in the intact pineal gland. The investigation of this and other regulatory processes in the pineal may be facilitated by the development of an *in vitro* system in which serotonin synthesis persists. Previous investigators have grown mammalian pineal glands in organ and tissue culture<sup>6-10</sup>, and have shown that the cells which appear bear a histological resemblance to pineal parenchymal cells<sup>9</sup>. The biochemical properties of pineal cells in culture, however, have not been examined yet. The present communication describes a technique for cultivation of the pineal glands of adult rats, such that serotonin is synthesized from the amino-acids tryptophan and 5-hydroxytryptophan with a rate that increases during the first 4 days in culture. Additional investigations provide evidence for the continuing activity of both the enzymes required for serotonin synthesis (tryptophan hydroxylase and 5-hydroxytryptophan decarboxylase), and for a rate-limiting role of tryptophan hydroxylase in the formation of this amine.

Sprague-Dawley female rats weighing 160-180 g were killed by neck fracture, and the pineal glands were quickly removed<sup>2,4</sup> and transferred to a Petri dish, where they were covered with neutralized Hanks solution. The gland was then divided into two approximately equal parts. These fragments were clotted to the walls of a Wasserman tube (which had previously been coated with a thin film of chicken plasma) by the application of chick embryo extract to the glass surface<sup>11</sup>. Fifteen to thirty minutes later, when the clot was sufficiently firm, 0.5 ml. of nutrient medium was added to the culture; the tube was sealed with a rubber stopper and incubated in a roller wheel at 37° C. The nutrient medium consisted of 75 per

cent Puck N 16 medium, 5 per cent Evans NCTC 109 medium, 10 per cent foetal calf serum and 10 per cent heat-inactivated (56 per cent C for 30 min) horse serum. The constituents of the medium were obtained as standard preparations, except for the N 16 and NCTC 109, which were prepared without phenol red. (This indicator dye had been found in preliminary experiments to interfere with the assay for serotonin.) The nutrient medium as described contained tryptophan in a concentration of approximately 10<sup>-4</sup> molar, but not 5-hydroxytryptophan. For certain experiments the medium was fortified with 10<sup>-3</sup> molar tryptophan or 10<sup>-5</sup>-10<sup>-3</sup> molar 5-hydroxytryptophan. At 2 day intervals the media were poured off and stored at -70° C for serotonin assay; new media were added, and the incubation was resumed. Each tube contained 25 U of penicillin, 25 µg of streptomycin, and 0.5 µg of amphotericin B ('Fungizone'). Each experimental group contained seven culture tubes.

All assays for serotonin were performed on the same day on 0.1 ml. aliquots of medium. The method of assay involved the formation of a fluorescent product after extracting the serotonin<sup>12</sup>. The identity of the serotonin was confirmed by thin-layer chromatography in an ethanol : dioxane : benzene : ammonia system (5 : 40 : 30 : 5), followed by staining with Ehrlich's reagent.

Cells in explanted pineal fragments had a healthy appearance throughout the 10 day period of observation. Examined in preparations stained with haematoxylin and eosin, the cell population after the first 2-3 days appeared to consist almost entirely of pinealocytes. There was little cellular outgrowth from the explanted fragments until the fourth day; however, by the eighth to tenth day an extensive growth appeared from all fragments. This outgrowth also consisted almost entirely of pinealocytes, with occasional scattered, more elongated cell forms. These morphological findings were similar to those described<sup>9,10</sup> in plasma clot cultures of rat pineal fragments, except that the outgrowth in the present investigation included fewer cells other than pinealocytes.

The net synthesis of serotonin by the pineals was determined by comparison of the quantity of amine released into the medium during 2 day periods of incubation with the amounts present in two kinds of control tubes: "zero-time" tubes, which were frozen immediately after the addition of the pineal, and tubes which were incubated without pineal tissue. When incubated with 0.5 ml. of medium containing 10<sup>-4</sup> molar tryptophan, pineals were capable of synthesizing as much as 1.5 µg of serotonin in a day. (This amount is several times greater than the highest reported concentrations of serotonin in the rat pineal, but is consistent with the rapid rate at which the serotonin content of the gland normally increases *in vivo* early in the day<sup>1</sup>). The medium did not contain 5-hydroxytryptophan, and so the synthesis of serotonin in these conditions indicated that the pineal gland contained both the 5-hydroxylating and the decarboxylating enzymes (that is, tryptophan hydroxylase and 5-hydroxytryptophan decarboxylase). The rat pineal has previously been shown to contain relatively large amounts of this latter enzyme<sup>13</sup>. Tryptophan hydroxylase activity has already been found in brain<sup>14</sup>, but not so far in the pineal.

To determine which of these two enzymes controlled the rate of serotonin synthesis by pineals in organ culture, glands were incubated with media fortified by the addition of tryptophan or 5-hydroxytryptophan (Table 1). Pineals incubated with 10<sup>-4</sup> molar tryptophan generated 4.3 × 10<sup>-9</sup> moles of the amine during the first 2 days of culture. (This represented an 8.5 per cent conversion of the amino-acid.) Increasing the concentration of the tryptophan ten-fold (to 10<sup>-3</sup> molar) did not increase the absolute yield of serotonin. Pineals incubated with 10<sup>-5</sup> molar 5-hydroxytryptophan generated 3.8 × 10<sup>-9</sup> moles of the amine in 2 days. When a greater concentration of this amino-acid was used, there was a marked rise in the rate of serotonin

synthesis (Table 1). These data indicated that the activity of the decarboxylase enzyme was considerably greater than that of the hydroxylating enzyme. They further suggested that, in the conditions of this experiment, the hydroxylation step determined the rate at which serotonin was formed.

Table 1. SEROTONIN SYNTHESIS BY RAT PINEAL GLANDS IN ORGAN CULTURE

Contents of medium	Moles of serotonin formed ( $\times 10^{-6}$ )/tube	Zero time	0-2 days	2-4 days
Tryptophan				
10 <sup>-4</sup> molar	1.0 $\pm$ 0.1	4.3 $\pm$ 0.3*	1.6 $\pm$ 0.2†	
10 <sup>-3</sup> molar	0.9 $\pm$ 0.2	4.3 $\pm$ 0.4*	3.8 $\pm$ 0.9†	
10 <sup>-4</sup> molar, no pineal	0.9 $\pm$ 0.1	0.9 $\pm$ 0.1	0.8 $\pm$ 0.1	
5-Hydroxytryptophan (also contained 10 <sup>-4</sup> molar tryptophan)				
10 <sup>-4</sup> molar	1.1 $\pm$ 0.2	3.8 $\pm$ 0.4*	2.8 $\pm$ 0.3*	
10 <sup>-3</sup> molar	1.6 $\pm$ 0.3	6.5 $\pm$ 0.6*	8.1 $\pm$ 0.6*	
10 <sup>-4</sup> molar	1.6 $\pm$ 0.3	9.9 $\pm$ 0.6*	10.9 $\pm$ 0.8*	
10 <sup>-3</sup> molar, no pineal	1.4 $\pm$ 0.1	1.5 $\pm$ 0.2	1.4 $\pm$ 0.1	

Groups of seven culture tubes, each containing one pineal gland, were incubated for 2 days. The medium was then poured off and frozen, fresh medium was added, and the tubes were incubated for 2 more days. Control tubes were frozen immediately after the addition of the pineal, or were incubated without a pineal. Aliquots of the culture medium (0.1 ml.) were assayed for serotonin content.

\* $P < 0.001$ , differs from zero time controls.

† $P < 0.01$ , differs from zero time controls.

In all experiments, the synthesis of serotonin from 5-hydroxytryptophan was greatest on days 2-4. Significant, but decreasing, amounts of the amine continued to be formed for 8-10 days after initiation of the culture. The increase in decarboxylase activity between days 0-2 and 2-4 suggests that new enzyme is being formed in organ culture. This could represent more enzyme in each pineal cell, or unchanged levels in a larger number of cells.

Previous work has shown that the activity of 5-hydroxytryptophan decarboxylase in the rat pinealocyte is regulated by the sympathetic nerves to this organ<sup>15</sup>. It is presumed that the sympathetic nerve ending exerts its effects by release of a neurotransmitter substance. The development of an *in vitro* system which continues to synthesize serotonin for several days could provide a useful experimental tool for investigation of the neural control of pineal enzymes.

## 1-Amino-4-phenyl Pyridinium Chloride: a Potential Antihypertensive Agent

DURING investigations of the synthesis, storage and release of peripheral catecholamines, 1-amino-4-phenyl pyridinium chloride (AH.2035) was found to cause a marked depletion of noradrenaline in mouse heart. The results reported here suggest that the compound (I) may be a useful antihypertensive agent.

Acute oral toxicity values for AH.2035A in different species are given in Table 1.

Table 1. ACUTE TOXICITY OF AH.2035A IN MOUSE, RAT, RABBIT, CAT AND DOG

Species	Mouse	Rat	Rabbit	Cat	Dog
Oral LD <sub>50</sub> (mg/kg)	161	713	150-300	> 75*	> 75*
(95 per cent fiducial limits)	(132-196)	(570-891)			

\* Oral doses of 150 mg/kg caused vomiting.

The noradrenaline contents of various organs in the mouse and rat were determined after acute and sub-acute oral administration of AH.2035A. Noradrenaline was extracted, isolated by ion exchange chromatography<sup>1</sup> and determined fluorometrically by a modification of the trihydroxy-indole reaction (Martin, L. E., and Harrison, C., to be published). In the mouse a single dose of AH.2035A (10 mg/kg) lowered the heart noradrenaline content by 66 per cent. In the rat repeated administration of AH.2035A (three doses of 5 mg/kg in 24 h) lowered the heart noradrenaline by 50 per cent. In neither experiment was the concentration of noradrenaline in the brain significantly affected. Thus, AH.2035A depletes peripheral but not central stores of noradrenaline in mouse and rat.

In dogs anaesthetized with pentobarbitone, AH.2035A injected intravenously in doses of 0.25-1 mg/kg produced pressor responses of 25-130 mm mercury which lasted for 10-45 min. After 1 mg/kg the rise in blood pressure was followed by a gradual fall to 50 mm below the pre-injection level during the next 2 h. The pressor responses to occlusion of the common carotid arteries or injection of tyramine were reduced throughout this period but that to noradrenaline was potentiated. The pressor effects of AH.2035A were prevented by previous treatment with reserpine, cocaine or phentolamine but not by hexamethonium. These effects are similar to those produced by guanethidine<sup>2</sup> in anaesthetized animals. AH.2035A differs, however, from guanethidine in that it does not cause acute adrenergic blockade. For example, AH.2035A did not block the inhibitory effects of sympathetic nerve stimulation in a Finkleman rabbit ileum preparation<sup>3</sup>.

Daily oral administration of AH.2035A in doses of 5 mg/kg to renal hypertensive dogs caused a pressor response on the first day of administration but not on subsequent days. On the second and third days of administration there was a gradual reduction in the mean arterial blood pressure of 30-40 mm mercury. When small doses of AH.2035A were given initially, and slowly increased to 5 mg/kg/day, only an antihypertensive effect was found. In this experiment as little as 1-2 mg/kg/day AH.2035A induced a significant reduction in systolic blood pressure. The antihypertensive action of AH.2035A in renal hypertensive dogs was not accompanied by diarrhoea or other noticeable side-effects.

The mechanism of the antihypertensive action of AH.2035A is not known for certain but is probably related to its action on stores of catecholamine in sympathetic nerve endings. The properties of AH.2035A and

its analogues are being investigated in greater detail and the results will be reported elsewhere.

### Activation of Tyrosine Hydroxylation in Rat Brain *in vivo* by Chlorpromazine

PHENOTHIAZINES and related neuroleptic drugs, such as thioxanthenes, markedly increase the content of homovanillic acid (3-methoxy-4-hydroxyphenylacetic acid) in the brain, especially in the extrapyramidal centres of various animal species. This has raised the question of whether neuroleptic drugs accelerate the synthesis of catecholamines through a feed-back mechanism either as a result of blockade of dopaminergic and noradrenergic receptors or of alteration of the amine storage<sup>1-6,16</sup>. The present communication shows that *in vivo* chlorpromazine and related neuroleptics markedly enhance the hydroxylation of tyrosine which seems to be a rate-limiting step in the formation of catecholamines<sup>7</sup>.

In female rats weighing 60–80 g, injected subcutaneously with 0.2 mg/kg L-3,5-<sup>3</sup>H-tyrosine (11.1 mc./mg), the <sup>3</sup>H-catechol derivatives of brain (homogenized in three volumes of 4 normal perchloric acid) were isolated by chromatography on alumina and measured in a liquid scintillation counter<sup>8</sup>. The endogenous tyrosine in blood plasma and brain stem (including basal ganglia, but without medulla and pons) was determined by a spectrofluorimetric method<sup>9</sup> which showed a similar recovery of added tyrosine (78 ± 5 per cent) in normal rats and rats treated with chlorpromazine. The animals receiving chlorpromazine (10 mg/kg intraperitoneally) were kept at an environmental temperature of 31° C in order to prevent a decrease of the body temperature

Fig. 1. Tyrosine hydroxylation in rat brain after a single intraperitoneal injection of 10 mg/kg chlorpromazine. <sup>3</sup>H-Tyrosine was administered subcutaneously to all animals 1 h before killing them. Controls (0 time) received <sup>3</sup>H-tyrosine only. Each point represents an average value with standard error; the number of experiments (each with a pool of two rats) is indicated beside the points.

Fig. 2. Tyrosine content in the brain stem and blood plasma of rats after a single intraperitoneal injection of 10 mg/kg chlorpromazine. Each point represents a mean of between eight and fifteen determinations of a pool of six animals ± S.E. Absolute values of controls (thirty-two experiments): brain stem 5.0 ± 0.1 µg/g; blood plasma 4.0 ± 0.2 µg/ml.

(maximal deviation from the normal rectal temperature of 1°–2° C as measured by a thermocouple).

In rats receiving <sup>3</sup>H-tyrosine, chlorpromazine increased the formation of <sup>3</sup>H-catechol derivatives in the brain by 80–100 per cent for a period of 1.5–6 h (Fig. 1). The total radioactivity of the brain, however, did not change significantly, which indicates that the penetration of tyrosine into the brain was not altered by the drug. The concentration of endogenous tyrosine in brain stem and blood plasma was significantly diminished by 20 and 30 per cent, respectively, 1–5 h after the treatment with chlorpromazine (Fig. 2), thus showing an inverse time course as compared with that of <sup>3</sup>H-catechols. These alterations may be characteristic for chlorpromazine-like neuroleptics, because chlorprothixene also enhanced the transformation of <sup>3</sup>H-tyrosine into <sup>3</sup>H-catechols and decreased the concentration of endogenous tyrosine. Other psychotropic drugs, however, such as imipramine, phenobarbitone and chlordiazepoxide, were less effective.

The increased transformation of <sup>3</sup>H-tyrosine into <sup>3</sup>H-catechols in the brain of intact rats indicates that chlorpromazine and chlorprothixene enhance the hydroxylation of tyrosine. It remains to be determined whether these neuroleptics act by a direct activation of tyrosine hydroxylase or by an indirect mechanism, for example, facilitation of tyrosine transport, enhancement of the turnover of catecholamines as a result of interference with catecholaminergic receptors or storage sites<sup>1,3,4,6</sup>. The decrease of endogenous tyrosine in brain and blood might, in part, result from the increased formation of catechol derivatives, but an additional activation of other pathways of tyrosine metabolism, for example, transamination<sup>10–12</sup>, must also be considered. The enhanced formation of <sup>3</sup>H-catechol and the diminution of endogenous tyrosine do not, however, seem to result from an alteration of protein synthesis, because this was not found to be affected by chlorpromazine in the brain of normothermic rats<sup>13</sup>.

In conclusion, an acceleration of the hydroxylation of tyrosine, which is considered to be a limiting step in the biosynthesis of catecholamines *in vivo*, might be connected with the increase of cerebral homovanillic acid due

to neuroleptic drugs. Furthermore, an enhanced synthesis of dihydroxyphenylalanine (DOPA) is possibly related to an increased formation of melanin observed in patients under prolonged treatment with neuroleptics<sup>6,14,15</sup>.

### Gel Filtration Radioimmunoassay to distinguish Human Chorionic Gonadotrophin from Luteinizing Hormone

EXISTING immuno- and bio-assays are incapable of readily distinguishing human luteinizing hormone (LH) from human chorionic gonadotrophin (HCG). A procedure capable of making this distinction should make it possible to solve a variety of problems, including whether the high levels of luteinizing activity associated with seminoma are due to HCG or LH, whether the blood of newborn infants contains HCG or LH, and whether or not moderately high levels of "LH" found by radioimmunoassay in patients thought to be cured of choriocarcinoma represent a recurrence of the neoplasm. The present communication describes a means for making this distinction. Advantage was taken of the different gel filtration properties of these two hormones to effect their separation, and the resulting elution peaks were then located by radioimmunoassay.

All the steps of the procedure were carried out at 4° C. The separation was performed in a 1.5 × 80 cm column of 'Sephadex G-100' which was equilibrated with 0.05 molar phosphate buffer at pH 7.6 and eluted in the same buffer at a rate of 5 ml./h using a peristaltic pump. Samples (1 ml.) were applied beneath the buffer on the surface of the gel, and sucrose was added as required to aid in the transfer. 1 ml. portions were collected in conical centrifuge tubes, and collection began when 0.5 ml. of sample had entered the gel. Blue dextran with a molecular weight of  $2 \times 10^6$  was used to determine the excluded or void volume ( $V_0$ ) and was measured by spectrophotometry at 630 mμ. HCG and LH were quantitated in the tubes by radioimmunoassay<sup>1</sup>. After gel filtration, 0.5 ml. of 1:80,000 anti-HCG in 1:400 normal rabbit serum containing 0.02 molar ethylenediamine tetraacetic acid (EDTA) in 0.14 molar saline buffered at pH 7.0 with 0.01 molar phosphate was added to each tube. After 24 h of continuous agitation, 0.5 ml. of HCG labelled with iodine-131 was added, followed 24 h later by 0.5 ml. of sheep anti-rabbit gamma globulin, the latter in a dilution which maximally precipitated the rabbit globulin in each tube. After incubation for 48 h each tube was centrifuged, decanted and counted. The elution volume ( $V_e$ ) for LH and HCG was determined by finding the tube which gave maximal inhibition of the reaction between the labelled HCG and its antibody. All results were expressed as the

ratio of  $V_e/V_0$  after subtracting the "dead" volume between the bottom of the gel column and the tip of the delivery tube in the fraction collector. In separate experiments, 1 ml. of serum containing HCG labelled with iodine-131 and LH labelled with iodine-125 was passed through the column and the hormones located by differential gamma-ray spectroscopy. The samples which contained HCG were made up from sera from pregnant women and serum from a woman with choriocarcinoma. The samples containing LH consisted of sera from women during the menstrual cycle<sup>2</sup>. Unknown samples consisted of sera from the umbilical vein of newborn infants.

The results are listed in Table 1. HCG could readily be distinguished from LH. The sensitivity of the radioimmunoassay procedure allowed the determination to be made on 1 ml. aliquots of serum from normal menstruating females at mid-cycle. The radioiodinated hormones gave  $V_e/V_0$  ratios indistinguishable from those of unlabelled hormones, but their elution peaks were sharper than those measured by radioimmunoassay for the endogenous hormones in sera. It is possible that some of the circulating hormones are bound to serum proteins.

Table 1. SEPARATION OF HCG AND LH BY GEL FILTRATION

	No. of samples	$V_e/V_0$
		Mean $\pm$ S.E.M.
Samples containing LH		
LH- <sup>125</sup> I	3	1.49 $\pm$ 0.02
Sera, women at midcycle	3	1.52 $\pm$ 0.04
Samples containing HCG		
HCG- <sup>131</sup> I	3	1.25 $\pm$ 0.07
Sera, pregnant women	2	1.32 $\pm$ 0.03
Sera, patient with choriocarcinoma	1	1.35
Unknown samples		
Sera, newborn infants	3	1.31 $\pm$ 0.01

Radioimmunoassay of three sera obtained from the umbilical vein of infants at the time of delivery by caesarean section showed that the hormone levels were comparable with those of non-pregnant adults. Analysis of these sera by gel filtration and radioimmunoassay showed that they contained a material with a  $V_e/V_0$  similar to that of HCG and not of LH (Table 1). Accordingly, it seems that a small amount of HCG normally enters the foetal circulation (concentrations of maternal HCG, 7–22 IU/ml., ranged from 570 to 800 times higher than those in the newborn babies).

We thank Dr. W. D. Peckham for the gift of purified human LH used for radioiodination (potency,  $5.3 \times$  NIH-LH-S1; lot No. WDP-VII p. 833).

This investigation was supported by a grant from the National Cancer Institute, U.S. Public Health Service. A. R. M. thanks the National Institute of Child Health and Human Development, U.S. Public Health Service, for a career development award, and R. B. J. the Josiah Macy Jr. Foundation for a faculty fellowship.

### Hypothesis on the Mode of Conversion of Glucose into $\alpha$ -Glucose-1-phosphate

SOME 10 years ago much evidence had accumulated that phosphorylase does not synthesize glycogen from  $\alpha$ -glucose-1-phosphate *in vivo*. The confirmation of this belief came with the discovery of glycogen synthetase,

and its synthesis of glycogen from uridine diphosphate glucose (UDPG)<sup>1</sup>. There is now a parallel situation in another area of glycogen metabolism, namely, repeated evidence from tracer experiments that the conversion of glucose into glycogen in liver and muscle does not proceed by way of glucose-6-phosphate. Several reports, originating with Beloff-Chain *et al.*<sup>2</sup> and most recently by Threlfall<sup>3</sup>, combine to indicate that there is a pathway from glucose to  $\alpha$ -glucose-1-phosphate—and thence to UDPG and glycogen—that does not have glucose-6-phosphate formation as an intermediate step. In other words, hexokinase, glucokinase, glucose-6-phosphatase acting in its synthetic role, all forming glucose-6-phosphate, together with phosphoglucomutase, converting the 6-phosphate into  $\alpha$ -glucose-1-phosphate, may well have no direct role in the conversion of glucose into glycogen.

It occurred to us that an answer to the problem might be found by examining the actions of two enzymes already known in muscle, namely,  $\alpha$ -glucose-1-phosphate kinase<sup>4</sup> and  $\alpha$ -glucose-1-phosphate dismutase<sup>5</sup>. These enzymes catalyse the following reactions

Both reactions have previously been studied in terms of their production of  $\alpha$ -glucose-1,6-diphosphate, the coenzyme of phosphoglucomutase. They may, however, serve a different purpose. Reaction (2) is reversible, and can be written as

If reactions (1) and (3) are added together we have

The whole system can be expressed as

Reaction (4) would be essentially irreversible because of the irreversibility of reaction (1). Experiments to test the hypothesis are in progress.

## Redox Pump Theory for Active Secretion of Hydrogen Ions

PERMIT me to bring to the notice of Professor Britton Chance and Leena Mela an obvious omission from the references to their paper<sup>1</sup> on proton movement in mitochondrial membranes. Is it possible that they can discuss the release of hydrogen ions at interfaces, associated with redox processes, without mentioning Conway's redox pump theory<sup>2</sup> for the active secretion of hydrogen ions by the cells of the gastric mucosa? Conway's theory, which predates other redox theories mentioned, specifically suggests electron transfer from flavoproteins to cytochromes as being particularly favourable for the active release of hydrogen ions from the cells of the gastric mucosa. He has also presented evidence<sup>3</sup> for a similar mechanism in fermenting yeast.

## BIOLOGY

### Pharmacodynamics of Dieldrin in Pigeons

CONSIDERABLE interest has been aroused in recent years by the presence of residues of organochlorine insecticides in the tissues of birds in Great Britain, and a comprehensive review of the situation up to 1965 has been made<sup>1</sup>. No information has been published yet on the pharmacodynamics of any of these compounds in birds. We are investigating this topic and some of our results are summarized in this report.

A group of pigeons was fed a diet containing 50 p.p.m. of the main constituent of technical dieldrin, that is, 1,2,3,4,10,10-hexachloro-6,7-epoxy-1,4,4 $\alpha$ ,5,6,7,8,8 $\alpha$ -octahydro-1,4-endo, exo-5,8-dimethanonaphthalene (HEOD) for 6 months. The pigeons were then fed a normal diet and killed at intervals. The concentrations of HEOD in the adipose tissue, brain, liver and breast muscle of the birds were determined by gas-liquid chromatography in combination with an electron capture detector. The results of the determinations are shown graphically in Figs. 1 and 2. It is apparent that HEOD was being eliminated from the body of the pigeons, and that the concentration of HEOD in the four body tissues was decreasing in an approximately exponential manner. Further, the rates of decrease of HEOD in the four tissues were similar.

The regression lines for the relationship between the concentrations of HEOD in the tissues (transformed to their corresponding logarithms) and time of feeding on the normal diet have been calculated; these are given in Table 1 and are also given in Figs. 1 and 2. An analysis of covariance<sup>2</sup> of the transformed results shows that the four rectilinear regression lines fit the data satisfactorily (that is, the mean squares of the deviations from linearity are not significantly different from the within group mean squares) and that there is no significant departure from parallelism. Consequently the pooled slope of the regression lines can be calculated. This pooled slope is  $-0.0064$  (confidence limits,  $P=0.95$ ,  $0.0055-0.0073$ ). The concentration of HEOD in these four tissues has been decreasing in parallel and so it can be postulated that the total content of HEOD in the whole bodies of the pigeons has been declining at this rate. Consequently the change

of concentration of HEOD in the whole pigeon when exposure ceases can be represented by

$$C_t = C_0 e^{-bt}$$

where  $b$  is 0.0064 and  $C_0$  is concentration of HEOD when exposure ceased.

The biological half-life of HEOD in the pigeon can be calculated from the relationship  $t_{1/2} = (\log_{10} 2)/b$ , whence the estimated mean half-life is found to be 47.2 days (confidence limits,  $P = 0.95$ , 41.4–54.9 days).

The intercepts of the calculated regression lines give an estimate of the concentration of HEOD in the four tissues after feeding on a diet containing 50 p.p.m. of HEOD for 6 months. These estimates are given in the fourth column of Table 1. The intercepts for the four tissues are significantly different and are in the order of fat > liver > muscle > brain. Using the concentrations in the four tissues the storage ratio, concentration of HEOD in tissue/concentration of HEOD in diet, can be calculated, and these estimates of the tissue storage ratios are given in column 5 of Table 1. The concentrations of HEOD in these four tissues of living pigeons are considerable and it is noteworthy that they are much higher than those found in the tissues of the majority of dead birds which have been analysed.

Table 1. CONCENTRATIONS OF HEOD IN THE BODY TISSUES OF PIGEONS AS A FUNCTION OF TIME AFTER TERMINATION OF EXPOSURE

Tissue	Regression line $y = bt + a$	Bio- logical half-life (days)	Estimate of concentration in tissue when feeding with HEOD was termi- nated (p.p.m.)	Storage ratio
Fat	$y = -0.007359t + 3.9620$	40.9	448.6	9.0
Liver	$y = -0.008183t + 2.9354$	48.7	32.7	0.65
Muscle	$y = -0.008782t + 2.7559$	44.4	16.3	0.33
Brain	$y = -0.005269t + 2.3932$	57.1	7.7	0.15

Pigeons had been fed a diet containing 50 p.p.m. of HEOD for 6 months.  $y = \log_{10}$  (concentration in p.p.m. of HEOD in tissue  $\times 10^4$ );  $t$  = time in days after ingestion of HEOD diet ceased.

The parallel decline in the various tissues is noteworthy, because it indicates that a dynamic equilibrium exists between the concentrations of HEOD in these tissues, an equilibrium that arises, no doubt, from the circulation of HEOD in the blood. It is plausible, therefore, that

Fig. 1. The change of concentration of HEOD in the fat and muscle of pigeons, which have been fed 50 p.p.m. of HEOD for 6 months, after dietary intake of this compound had ceased. ●, Fat; ○, muscle.

Fig. 2. The change of concentration of HEOD in the brain and liver of pigeons, which had been fed a diet containing 50 p.p.m. of HEOD for 6 months, after dietary intake of this compound had ceased. ●, Liver; ▲, brain.

the dynamics of uptake, distribution and elimination of HEOD in birds agree with the compartmental model that has been used to explain the pharmacodynamics of drugs in experimental animals and man<sup>3,4</sup>. Furthermore, an elimination mechanism of the exponential type, demonstrated for HEOD in our experimental pigeons, implies that continuous uniform exposure of pigeons (and, presumably, other bird species) will result in an equilibrium concentration in the tissues in accordance with an asymptotic relationship of the type  $C_t = C_{eq} (1 - e^{-bt})$ , where  $C_t$  is the concentration after exposure for time  $t$ ,  $C_{eq}$  is the asymptote ( $C_t \rightarrow C_{eq}$  as  $t \rightarrow \infty$ ), and  $b$  is the slope of the regression line for the elimination process when the concentrations are transformed to their corresponding logarithms. In the case of exposures that vary in a random manner over a period of time, the equilibrium concentration will vary within limits dependent on the variations of the exposure.

As in the case of mammals there will certainly be inter-specific variations in the half-life of HEOD in birds, in the ratios of concentrations of HEOD in the various tissues, and in the storage ratios for the tissues. All these factors, however, have implications of great importance in the assessment of the potential hazards to the general bird population arising from the use of dieldrin in agriculture. First, the concentrations of HEOD in any tissue may be used as an index of chronic exposure and consequent pharmacological effects. Second, the significant variations between tissues in the storage of HEOD indicate that the concept of transfer of HEOD along food chains with concomitant biological amplification requires more precise definition than has been given so far. Third, the ability to eliminate HEOD from the body is of importance in all birds, but particularly for wood-pigeons and other grain eating birds which may have seasonally varying exposures as a result of agricultural practice. Reports of increased mortality of wood-pigeons, for example, were made in the years 1956–61 and the deaths of these birds were attributed to the use of cereal seed dressed with, for example, dieldrin<sup>5</sup>. A detailed investigation of the dynamics of a wood-pigeon population in Cambridgeshire has been made by Murton and his co-workers<sup>6-8</sup> and this included an investigation of the effects of dressed cereal seed on the wood-pigeons

in 1961 (ref. 10). The breeding population in the area investigated was about 20 per cent smaller than normal in the spring of 1961 and an estimated mortality of at least 8 per cent was attributed to poisoning by toxic chemicals. The decline in the breeding population was not statistically significant, but there were other indications that the 1961 breeding population was abnormally low. The population numbers, however, had recovered in 1962 and so the effects of the apparently low breeding stock in 1961 were transitory. Samples of tissues from many of the dead birds collected in the spring of 1961 contained large amounts of HEOD and other organochlorine insecticides\* and it is highly probable that the surviving birds also had large, albeit non-fatal, body burdens of HEOD. The ability of the birds to eliminate HEOD between the breeding seasons was probably an important factor in the transitory nature of the effect of dieldrin on the population dynamics of the wood-pigeons in that area.

## Oviposition Responses by Aphidophagous Syrphidae (Diptera)

CURRENT work on syrphid predators of aphids has demonstrated some behavioural responses of the ovipositing adult females which may be significant in relation to a general understanding of natural enemy action and also to the better use of natural enemies in the control of insect pests.

Females of aphidophagous Syrphidae oviposit close to aphids<sup>1-3</sup> and only very rarely on uninfested plants<sup>4-6</sup> when they lay single<sup>7,8</sup>, usually sterile<sup>9</sup>, eggs. I have found, however, that the age of the syrphid and the species may greatly affect oviposition behaviour. There is substantial variation in the rate of ageing, at least under caged conditions, but results for one experiment, showing a particularly marked decline in precision of response with age, are presented in Table 1, which demonstrates how the mean distance between the eggs laid by *Syrphus luniger* Mg. and the nearest aphid (*Brevicoryne brassicae* L. on brussels sprouts) increased as the syrphids aged.

This change in behaviour could be explained by a loss of discrimination by the female and/or by stimulus satiation. The loss of precision from stimulus satiation

should be reversible, whereas loss of discrimination through ageing would be irreversible.

When the stimulus (that is, the infested plants) was removed on the eighth day and replaced on the fourteenth day there was only a slight restoration of precision (Table 1). Furthermore, by the twentieth day, *S. luniger* females were laying eggs, still mostly fertile, on uninfested plants even in the presence of infested ones, and it is concluded that while there may have been some stimulus satiation, the chief cause of the reduction in precision was a loss of discrimination with age, which began immediately after the first oviposition.

A predator which is attracted to the host plant of the aphid and can oviposit in advance of infestation, or when the population of the prey is still very small, is likely to affect the number of the prey more and to be more useful in biological control than one which, however voracious, is attracted only by relatively large numbers of the prey. It may be that the failure of discrimination in ageing species of *Syrphus* directly increases their efficacy in natural control by providing increased predatory power on incipient aphid infestations on plants where the aphid stimulus would normally be inadequate to induce oviposition.

I have repeatedly observed the species *Platychirus peltatus* Mg. and *Melanostoma scalare* L. to lay fertile eggs in significant numbers on uninfested plants, apparently in response to the host plant of the aphid and not to the aphid itself. They would seem to be potentially more useful than *Syrphus* species for controlling aphids at an early stage of infestation.

## Production of Dauer Pupae in *Bombyx mori* L.

THE average pupal period of silkworms is about 12-15 days at 25° C. When the brains of some strains are extirpated immediately after pupation, however, imaginal differentiation is not detectable for as long as 100-200 days, and these brainless pupae have been called "dauer pupae"<sup>1</sup>. The extent to which dauer pupae can be produced differs according to race and strain, but the reason for this is not known. With a cross between *J.122* and *C.115*<sup>1</sup> and the original race *C.R.*<sub>4</sub> (Morohoshi; unpublished results) the production of between 50 and 70 per cent dauer pupae was achieved by extirpation of the pupal brain.

Using silk thread, we ligatured hybrid larvae (*Bm* × *N.*<sub>24</sub>) 2 days before pupation in various ways, when the posterior parts of surviving silkworms developed into dauer pupae (Fig. 1), while the anterior parts died within 30 days of applying the ligature. Within the same race, some silkworms which had had either their brains extirpated immediately after pupation or their suboesophageal ganglion extirpated 2 days before pupation emerged as did untreated controls.

It would seem from these experiments that imaginal differentiation occurs when brain hormone is secreted in plenty, and that dauer pupae develop when the secretion is impaired. Accordingly it should be possible to produce dauer pupae in most strains by cutting off the secretion from the brain, provided the time of operation is correct.

Table 1. DECLINE IN PRECISION OF RESPONSE TO APHIDS IN OVIPOSITING FEMALES OF *Syrphus luniger* Mg.

Age of female from first oviposition (days)	Total No. of eggs laid	Percentage of eggs laid at stated distance from nearest aphid (mm)					
		0	1-5	6-10	11-15	16-30	30+
0-1	106	50.0	37.8	8.5	1.9	0.9	0.9
2-3	208	37.0	43.8	8.2	3.8	3.8	3.4
4-6	254	31.9	40.2	12.6	6.3	4.7	4.8
7-8	184	14.7	39.7	21.2	10.3	5.4	8.7
14-16	240	25.2	37.0	20.7	6.5	6.5	4.1

Fig. 1. "Dauer pupae" produced by ligaturing arvae of the second day before pupation in different regions: A, behind brain and before suboesophageal ganglion; B, behind suboesophageal ganglion and before prothorax; C, between pro- and mesothorax; D, between meso- and metathorax; E, between metathorax and abdomen. The photograph was taken after the "dauer pupae" had been kept at 25° C for 50 days after spinning their cocoons.

It is probable that in *Bombyx*<sup>1-3</sup> as well as in *Platy-samia*<sup>4-7</sup> the brain hormone stimulates the activation of the prothoracic gland which releases a hormone into the blood which initiates imaginal differentiation. It is possible that the strains in which dauer pupae occur by extirpation of the brain immediately after pupation, such as the hybrid between J.122 and C.115 or the original race C.R., resulted from a delay in the relative development of the pupae compared with other races.

### Function of the Brain through Nerve Commissures on the Suboesophageal Ganglion in *Bombyx mori* L.

Fukuda and Hasegawa have verified<sup>1-3</sup> that voltinism in the silkworm is probably controlled by a hormone from the suboesophageal ganglion. Hasegawa has claimed that voltinism may be determined by the function of the suboesophageal ganglion alone, while Fukuda has assumed that it may be determined by that of the brain-suboesophageal ganglion complex at the pupal stage. It can be inferred from Fukuda's experiments that the brain controls the secretion of the suboesophageal ganglion. When the brain completely suppresses the secretion of the suboesophageal ganglion, the silkworm moths lay batches of non-diapausing eggs. When the brain accelerates the secretion of the suboesophageal ganglion, on the other hand, the moths lay batches of diapausing eggs. Fukuda concluded that the centre which controls voltinism lies in the pupal brain. Morohoshi<sup>4</sup> later recognized that inhibitory and accelerating functions of the brain are not completely absent but act only weakly.

Table 1. PRODUCTION OF DIAPAUSE EGGS BY TRANSPLANTING BOTH THE SUBOESOPHAGEAL GANGLION AND BRAIN-SUBOESOPHAGEAL GANGLION COMPLEX

No.	Recipient J.106 x Di	Donor	Race	Non-dia- pausing moths	Moths laid mixed eggs	Dia- pausing moths	Season of experi- ment
1	Control (Wounded)	J.106		26	0	0	
2	L ← H (SG)	x		25	2	1	Spring
3	L ← H (Br+SG)	Di		15	8	1	(1965)
4	Control (Wounded)		K	28	0	0	
5	L ← H (SG)	x		12	2	6	Summer
6	L ← H (Br+SG)	Di		8	1	13	(1965)
7	Control (Wounded)	J.106		33	0	0	
8	L ← L (SG)	x		24	9	3	Autumn
9	L ← L (Br+SG)	Di		13	14	3	(1965)

L, Low incubating temperature; H, high incubating temperature.

Investigations of a *Kp* strain have indicated that the brain of this silkworm displays only an accelerating function and only ever produces batches of diapausing eggs regardless of the temperature of incubation: however, it seems possible that there are ecologically and developmentally different types of bivoltine races. A cross between a bivoltine strain and the *Kp* strain produced a hybrid the *F*<sub>1</sub> offspring of which when incubated at a low temperature (17° C) always revealed batches of non-diapausing eggs but no diapausing ones. The diapausing gene of the *Kp* strain was thus recessive<sup>5</sup>.

From a genetical analysis of the *Kp* strain.

it is known that the function of the suboesophageal ganglion is controlled by a major gene which also controls bivoltinism and that the brain accelerates the function of the suboesophageal ganglion through nerve commissures. If, as a result of incubation at a low temperature, the brain of this strain were to inhibit the function of the suboesophageal ganglion, some non-diapausing eggs would be expected. No batches of non-diapausing eggs, in fact, appeared at the low temperature of incubation. This may mean that there is no inhibitory function in the brain of the *Kp* strain. The *Kp* diapausing strain produced non-diapausing eggs when its brain was extirpated immediately after pupation.

It can be seen from experiments Nos. 7-9 of Table 1 that the "non-diapausing" hosts transplanted with brain-suboesophageal ganglion complex (*Br+SG*) from "non-diapausing" donors produced more diapausing moths than did the "non-diapausing" hosts transplanted with the suboesophageal ganglion alone (*SG*). This may result because the brain from the "non-diapausing" donor does not inhibit the secretion of the suboesophageal ganglion through nerve commissures, but weakly accelerates that of the suboesophageal ganglion.

### Oviposition of *Aedes aegypti* L. on a Dry Surface and Hygroreceptors

It is known that the mosquitoes *Culex* and *Anopheles* lay their eggs on water and that *Aedes* lays its eggs on wet surfaces. If a wet surface is absent, *Aedes* will not lay eggs<sup>1,2</sup> nor will *Culex*<sup>2</sup>. In *Anopheles*, however, some laying can be obtained on a dry surface<sup>2,3</sup>. When gravid females of *A. aegypti* were placed over a wet surface without being able to come into actual contact with it they laid a number of eggs on an interposed dry screen. An attempt was made to locate the hygroreceptors involved in oviposition.

In each of the experiments, twenty gravid *A. aegypti* were placed in a sieve of 80 mesh copper screen gauze. The sieve, with its top end covered with gauze, was placed over a Petri dish filled with wet filter paper to a thickness of about 1-1.25 cm. The filter papers were kept moist by the addition of water. The gravid mosquitoes were maintained at a temperature of 26° C and 70 per cent relative humidity for 3 days. At the end of this

period, no eggs were found on the top of the filter papers, but careful examination with a magnifying glass revealed white eggs irregularly scattered on that part of the screen which had been above the wet surface. These eggs did not darken but remained white and transparent because of the lack of contact with water. The number of eggs obtained in two such experiments was 120 and 150, that is, 6 and 7.5 eggs from each female, respectively.

Similar experiments were carried out with antennectomized (all flagellar segments removed) mosquitoes. The number of eggs obtained in six repeated tests was 102, 53, 71, 152, 71, 35—an average of four eggs from each female. Under normal conditions, the average number of eggs laid by each female on wet filter paper placed in a water container was found to be about a hundred for both intact or antennectomized mosquitoes. The only difference was that whereas intact mosquitoes laid most of their eggs (65 per cent) on the wet filter paper and the remainder on water, antennectomized mosquitoes laid most of their eggs (79 per cent) on the water and the remainder on the wet filter paper.

In two other tests, the proboscis was removed in addition to the antennae, in order to prevent any possible contact of the stylets (which are extremely fine) with the wet surface below. (It was thought that information concerning the existence of a wet surface might be obtained by means of the only organs that may come into contact with it.) Even under these conditions, thirty and ten white eggs were obtained in the two tests.

It has been shown that hygroreceptors in *A. aegypti* are located on the antennae<sup>4,5</sup>. The present experiments indicate that this mosquito possesses additional hygroreceptors on other parts of the body. They appear, however, to be far less sensitive than those located on the antennae, for Roth and Willis<sup>6</sup> have shown that when *A. aegypti* were given a choice of two relative humidities (75 per cent and 100 per cent) the lower humidity was preferred. This preference was progressively reduced when the antennal segments were removed, and was completely absent when all the flagellar segments were removed. Similarly, it has been shown<sup>6</sup> that intact female mosquitoes provided with water *ad libitum* avoided the air close to a wet surface, whereas similar antennectomized mosquitoes showed no reaction. It has also been found (unpublished results) that whereas intact mosquitoes easily locate inside their cage water contained in a jar with a 1 cm diameter hole in the centre of its cover, antennectomized mosquitoes cannot do so. When the first two flagellar segments of the antennae are retained, about 50 per cent of the mosquitoes are capable of finding the water; when the first three flagellar segments of the antennae are present the percentage rises to 90 per cent. It appears, therefore, that the hygroreceptors which are located on the body, other than on the antennae, are similar to what is known as "the common chemical sense" of insects. The receptors of the common chemical sense, the location of which is unknown, are far less sensitive to the odours than the olfactory receptors located on the antennae<sup>6</sup>.

The much smaller number of eggs laid by intact as well as antennectomized mosquitoes when prevented from coming into contact with the wet surface indicates that under normal conditions, that is, when the mosquitoes can freely contact water or wet surfaces, additional sense organs, probably moisture receptors, are involved in the process of oviposition.

## Response of Fungi to Diurnal Temperature Extremes

REPEATED freezing and thawing of bacteria is generally considered to be lethal<sup>1,2</sup>, but *Aerobacter aerogenes* and a *Pseudomonas* species have survived and grown well in experiments simulating Martian temperature extremes of about +25° C to -75° C (ref. 3). The bacteria spent only about 4.5 h above 0° C with a maximum near 25° C in each 24 h cycle. Growth rates in liquid media were found to be comparable with the non-cycled controls held at 25° C. In similar work with desert algal-lichen soil crusts<sup>4</sup>, the algae survived repeated freezing and thawing but did not grow during the treatment. The algae were grown later on a modified Pochon solution incubated at 27° C-30° C. The diurnal temperature extremes were -79° C or -195° C for 15 h and 22° C for 9 h for periods of 1-7 days. As far as is known, no comparable work has been done on the response of fungi to diurnal temperature extremes.

This report presents the results of a preliminary investigation of the response of various fungi to diurnal temperature extremes of -94° C to 23±2° C. The fungi were grown on malt agar (BBL) and two or four agar disks 10 mm in diameter were transferred to Petri dishes containing a sterilized University of California type soil mix. Each dish contained 50 g of air dried soil mix, 5 ml. of 1 per cent sterile glucose solution, and sufficient sterile water to bring the soil moisture to about 50 per cent field capacity at the beginning of the experiment and 38 per cent at the end. The dishes were then cooled to -94° C for 19.5 h in darkness in a Revco ultra low temperature freezer, removed from the freezer, and warmed to 23±2° C for about 4.5 h. The treatment lasted for 35 days. During the warming phase the dishes were exposed to 80±10 ft. candles of cool-white fluorescent light. The control dishes were kept at room temperature and, depending on the growth rate of the fungus, hyphae traversed the entire soil surface in 1 or 2 weeks. The rates of sub-zero warming and cooling experienced by the fungus were determined by placing a 36-gauge copper-constantan calibrated thermocouple on the soil surface and recording the temperature change on a temperature recorder (Fig. 1).

The treated dishes were examined under a Bausch and Lomb 'StereoZoom' microscope (at ×30) for hyphal growth during and after the thirty-five cycle treatment. Because of the small amount of mycelium produced at the

Fig. 1. Rate of temperature change of the soil mix surface during one 24 h cycle of warming and cooling. The minimum temperature is reached 11 h after the beginning of the warming and cooling phases.

end of the treatment, mycelial growth was arbitrarily measured from the edge of the agar plug to the farthest point of advance on the soil surface. It was recorded as no growth, growth less than 1 mm, or growth greater than 1 mm but less than 4 mm. Growth more than 4 mm was not observed. The results after the thirty-fifth cycle are shown in Table 1.

Table 1. RESPONSE OF VARIOUS FUNGI ON STERILE SOIL MIX TO DIURNAL TEMPERATURE EXTREMES

Organism	No growth	1 mm growth	1 mm-4 mm growth
<b>Phycomycetes</b>			
<i>Phytophthora</i> species	×		
<i>Rhizopus nigricans</i>	×		
<b>Ascomycetes</b>			
<i>Ceratocystis</i> species	*		
<i>Nectria cinnabarina</i>	*		
<i>Ophiobolus graminis</i>			×
<i>Pleospora herbarum</i>		×	
<b>Fungi imperfecti</b>			
<i>Alternaria dauci</i>			×
<i>Ascochyta pisi</i>		×	
<i>Curvularia</i> species		×	
<i>Dicoccum asperum</i>	×		
<i>Fusarium roseum</i>		×	
<i>Helminthosporium sativum</i>		×	
<i>Phoma</i> species			×
<i>Stachybotris atra</i>	×		
<i>Stemphylium ilicis</i>			×
<b>Myxomycetes†</b>			
<i>Physarum flavicomum</i>	×		
<i>Physarum gyrosum</i>	×		
<i>Physarum polycephalum</i>	×		

Growth was measured after the thirty-fifth cycle of  $-94^{\circ}\text{C}$  for 19.5 h and  $+23^{\circ}\text{C}$  for 4.5 h.

\* Organism grew after subsequent culture on potato dextrose agar incubated at  $25^{\circ}\text{C}$ .

† Subjected to one cycle only, death determined by lack of protoplasmic streaming, protoplasmic disorganization, and failure to recover after subsequent incubation at  $25^{\circ}\text{C}$ .

*Alternaria dauci* showed the greatest mycelial development of the fungi growing in excess of 1 mm but less than 4 mm (Fig. 2). Fungi that did not seem to grow during the treatment were tested for survival by incubating pieces of the agar plug at  $25^{\circ}\text{C}$  on potato-dextrose agar plates for 3 weeks. After 3 weeks incubation, the mycelia of *N. cinnabarina* and *Ceratocystis* species were well developed and did not differ morphologically from stock cultures. On the other hand, *Stachybotris atra*, *Rhizopus nigricans*, *Dicoccum asperum*, and *Phytophthora* species did not develop on potato-dextrose agar plates, and microscopic examination ( $\times 100$ ) failed to show germinating hyphae emanating from the agar plug pieces.

Fig. 2. Growth of *Alternaria dauci* on the soil mix surface after thirty-five diurnal warming and cooling cycles. Growth was limited but measurable. Arrow A points to the edge of the agar plug and arrow B indicates the furthest advance of the mycelium from the agar plug.

In separate experiments with slime moulds, the plasmodia of *Physarum polycephalum*, *P. gyrosum*, and *P. flavicomum* were cultured on 'Cellophane' strips and allowed to migrate over oatmeal agar overnight. The 'Cellophane' strips were then placed on the sterile soil mix surface and subjected to only one cycle. After the warming phase, the 'Cellophane' was removed from the soil mix surface and the plasmodium examined ( $\times 100$ ) for protoplasmic streaming. No movement was detected and the plasmodium appeared to be disorganized. The strips were then incubated on oatmeal agar for 1 week but the plasmodium failed to recover. These results are not surprising in view of the report<sup>5</sup> that the plasmodium of *P. polycephalum* is killed after a 5 sec exposure to only  $-1^{\circ}\text{C}$  or  $-2^{\circ}\text{C}$ .

The rates of cooling and warming experienced by the fungi (Fig. 1) were not constant and only an approximate value can be obtained. Between  $-94^{\circ}\text{C}$  and  $0^{\circ}\text{C}$  an approximate sub-zero warming rate of  $4^{\circ}\text{C}$  to  $5^{\circ}\text{C}/\text{min}$  can be calculated with a cooling rate of about  $1^{\circ}\text{C}$  to  $2^{\circ}\text{C}/\text{min}$  between  $0^{\circ}\text{C}$  and  $-40^{\circ}\text{C}$ . These rates compare favourably with the rates reported by many investigators (summarized by Mazur<sup>6</sup>) for the optimal survival of yeast cells suspended in distilled water and cooled to  $-30^{\circ}\text{C}$  or lower.

In those species of fungi that survived the exposure to diurnal temperature extremes but did not grow, growth on the agar plug may have occurred but was so limited that it was not detected. Data indicated, however, that certain fungi were able to survive and produce limited mycelial growth when exposed to simulated Martian diurnal temperature extremes. Although most of the hyphae and spores were probably killed after the first few cycles, resistant portions apparently succeeded in growing and adapting to this temperature regime.

I thank Drs. C. J. Alexopoulos, L. W. Durrell, and C. M. Leach for providing the cultures used in this work.

## Levels of Monoamine Oxidase in the Brain of C57BL/6J Mice after Exposure to Defeat

It has been widely demonstrated during the past several years that changes in brain levels of serotonin have a direct effect on changes in behaviour<sup>1-12</sup>. Norepinephrine has also been shown to be directly involved with behaviour<sup>9,13</sup>. In addition, norepinephrine has been demonstrated to be connected with the behavioural changes observed when an animal is attacking or being attacked<sup>14</sup>, and both serotonin and norepinephrine have been reported to be involved in the learning ability of mice<sup>15-17</sup>. These observations were all made after changing the brain amine levels by the administration of drugs or by electrically stimulating the brain. No work, however, has been reported to show the effect of purely behavioural manipulation on the brain amine levels.

Before the role of serotonin and norepinephrine in behaviour can be clarified, it is necessary to investigate the enzyme systems involved in their metabolism. With this in mind, an investigation of monoamine oxidase, the enzyme which oxidatively de-aminates serotonin and

norepinephrine, was undertaken to determine the effect on this enzyme of exposure to fighting aggression.

The animals used were mice of strain C57BL/6J. A colony of fighter mice was first trained according to the method of Scott<sup>18</sup> for use in fighting encounters with experimental mice.

The experimental mice were weaned and isolated at 21–25 days of age. After at least 40 days of isolation, these "naive" mice (not trained to fight) were exposed to trained fighters for 0 (unfought controls), 1, 4 or 8 five-minute periods in one day. Ten mice were each exposed at each of these periods. Twenty minutes after the last fight, the mice were killed by decapitation and the brains quickly removed; the hypothalamus, amygdala and frontal cortex were dissected out, frozen in acetone-dry ice and weighed to the nearest 0.1 mg. The three brain areas were kept frozen for future analysis.

Monoamine oxidase was assayed by a modification of the methods described by Wurtman and Axelrod<sup>19</sup> and McCaman *et al.*<sup>20</sup>. Twenty  $\mu$ l. of brain homogenate (1 g/25 ml. of water) was mixed at 0° C with 0.1 ml. of 0.8 mM 5-hydroxytryptamine-2-<sup>14</sup>C (in 0.1 M phosphate buffer of pH 7.2) and incubated at 38° C for 30 min. The reaction was stopped by the addition of 2.0 ml. of 2 N hydrochloric acid which also served as a wash to remove excess labelled substrate. The radioactive 5-hydroxy-indoleacetic acid formed in the reaction was extracted with 6 ml. ethyl acetate. Four ml. of the ethyl acetate was then transferred to a counting vial followed by 2 ml. ethyl alcohol and 10 ml. toluene scintillator solution. Each sample was run in triplicate and the enzyme units calculated by the following equation:

$$\frac{\mu\text{moles serotonin} = \text{converted/g tissue/h}}{(\text{N mmoles substrate}) (\text{counts of sample}) (2000)} \\ \frac{2/3 (\text{counts of N moles substrate}) (\text{g of sample})}$$

The results showed that monoamine oxidase exhibited different trends for each of the areas investigated (Table 1).

Table 1. EFFECT OF EXPOSURE OF NAIVE MICE TO TRAINED FIGHTERS FOR A DIFFERENT NUMBER OF 5-MIN PERIODS IN ONE DAY ON THE MONOAMINE OXIDASE ACTIVITY IN THE HYPOTHALAMUS, AMYGDALA AND FRONTAL CORTEX

Fights/day (No.)	Monoamine oxidase activity $\mu$ M serotonin/g/h		
	Hypothalamus	Amygdala	Frontal cortex
0	6.467	5.659	5.973
1	9.009	7.513	5.993
4	9.704	5.763	5.987
8	8.847	4.672	4.412

The normal value for the hypothalamus was found to be 6.467 enzyme units (one unit = the amount of enzyme contained in one g of tissue which converts one  $\mu$ mole of 5-hydroxytryptamine to one  $\mu$ mole of 5-hydroxy-indoleacetic acid in 1 h) which was higher, but not significantly, than the frontal cortex or the amygdala which had normal levels of 5.973 and 5.659 units, respectively.

After one fight, an insignificant increase was observed in the hypothalamus, to a value of 9.009 units. Four fights brought the monoamine oxidase activity of the hypothalamus to a value of 9.704 units, which was significantly ( $P < 0.05$ ) higher than normal, but not significantly different from the one-fight value. This was followed by a decrease after eight fights to a value of 8.847 units which was no longer significantly higher than normal.

The amygdala showed a significant ( $P < 0.005$ ) increase to a value of 7.513 units after one fight. The activity then returned to a normal value of 5.763 units after four fights, which was followed by a further decrease to 4.672 units after eight fights which was significantly ( $P < 0.05$ ) below normal.

No change was observed in the frontal cortex during the first four fights. After eight fights, however, a decrease below normal, to 4.412 units, was found which approached significance at the 0.05 level.

It is interesting that both the hypothalamus and amygdala show initial increases whereas the frontal

cortex is unaffected. This indicates a rapid use of the amines in the hypothalamus and amygdala. After eight fights, however, the monoamine oxidase activity of both the amygdala and frontal cortex decreased below normal while the activity in the hypothalamus remained slightly above normal. This could mean that an active mobilization of the enzyme and/or the amines was taking place from the amygdala and frontal cortex to other brain areas such as the hypothalamus. The high activity of monoamine oxidase in the hypothalamus also indicates that this is the area of greatest utilization of serotonin and norepinephrine.

It should be noted that several workers<sup>21–23</sup> have suggested that there may be different monoamine oxidases for different amines or that there may be more than one active site involved in the enzyme. If this is the case, since we used serotonin as the substrate in the enzyme analysis, the monoamine oxidase actually measured was that for serotonin.

### Resistance to Water Transport in Plants— a Misconception Misconceived

WE agree with Professor Levitt<sup>1</sup> that there is a valid objection to "van den Honert's law" but believe that the argument he develops is fallacious.

We assume that transport of liquid water through the plant is linearly related to differences in water potential and that vapour transport across the air filled spaces of the leaf is linearly related to differences in vapour pressure. This is essentially the point Professor Levitt makes. In a steady state, the flow of water may be represented by

$$f = \frac{P_r - P_w}{R_L} = \frac{p_w - p_a}{R_V}$$

where  $P_r$  and  $P_w$  are the water potentials at the root surface and the mesophyll cells,  $p_w$  and  $p_a$  the partial pressures of water vapour above the evaporating surface in the cell wall and ambient air, and  $R_L$  and  $R_V$  the resistances to flow in the liquid and vapour phases, respectively. Professor Levitt has ensured, by expressing  $P$  and

$p$  in similar pressure units, that  $R_L$  and  $R_V$  are dimensionally similar; however, nothing is learned by comparing their magnitudes since they refer to physically dissimilar phenomena. What is required is a comparison of the effect on flow of a relative change in  $R_V$  with a similar relative change in  $R_L$ . From the relation  $V_0 dP_w = v_0 dp_w$ , where  $V_0$  and  $v_0$  are the specific volumes of liquid water and water vapour respectively,

$$\frac{R_V}{R_L} \cdot \frac{(\partial f / \partial R_V) R_L}{(\partial f / \partial R_L) R_V} = \frac{R_V}{R_L} \cdot \frac{v_0}{V_0}$$

Professor Levitt discusses an example in which  $R_V/R_L = 1/2,500$ .  $v_0/V_0 = 33,000$  (at  $30^\circ\text{C}$ ), however, and thus a change in resistance to vapour flow will alter the transpiration rate 13 times more than a similar relative change in the resistance to liquid flow. van den Honert's argument exaggerates the relative importance of  $R_V$ ; nevertheless, his conclusion remains qualitatively correct. Indeed, were it not for this and the large energy requirement for vaporization, few land plants could survive.

### Resistance to Water Transport in Plants

DR. LEVITT<sup>1</sup> directly compares a resistance for flow of liquid water with one for gaseous diffusion of water vapour. A comparison of the resistances in the plant tissues with those in the gaseous phase is, however, only possible even as an approximation if both are expressed in terms of the same fluid. If this comparison is made in terms of water vapour we can specify, for each part of the system that is considered separately, an equivalent air path; this is a tube of air of unit cross-sectional area of such a length that, with the equivalent potential difference ( $\Delta P$ ) maintained between its two ends, it would allow the same net flow of water as that observed to pass through the system in the steady state.

For diffusion of water vapour in such a tube of air

$$\frac{P_T V}{t} = \frac{K.A.(P_1 - P_2)}{l}$$

where  $P_T$  is the total pressure (atm),  $\frac{P_T V}{t}$  is the volume ( $\text{cm}^3$ ) of water vapour calculated as at unit pressure passing through the tube in time  $t$  (sec),  $K$  is the diffusion coefficient for water vapour ( $\text{cm}^2 \text{sec}^{-1}$ ),  $A$  is the cross-sectional area ( $\text{cm}^2$ ) and  $l$  is the length (cm) of the tube and  $P_1 - P_2$  is the difference in partial pressure (atm) of aqueous vapour between the two ends. The rate of flow  $\frac{P_T V}{t}$  is thus in terms of  $\text{cm}^3 \text{sec}^{-1}$  of aqueous vapour calculated as at unit pressure and at the temperature of the experiment. The resistance is

$$\frac{(P_1 - P_2)t}{P_T V} = \frac{l}{KA} = R \text{ sec cm}^{-3} \quad (1)$$

The expression used by van den Honert<sup>2</sup> was

$$\frac{dm}{dt} = \frac{P_1 - P_0}{R_r} = \frac{P_2 - P_1}{R_x} = \frac{P_3 - P_2}{R_l} = \frac{P_4 - P_3}{R_g}$$

or for the whole system

$$\frac{dm}{dt} = \frac{P_4 - P_0}{R_r + R_x + R_l + R_g} \quad (2)$$

Here  $dm/dt$  (in unspecified units) was the rate of water transport in the steady state,  $P_1 - P_0$  to  $P_4 - P_3$  were potential differences in terms of diffusion pressure deficit (atm) and  $R_r$ ,  $R_x$ ,  $R_l$  and  $R_g$  were resistances (again in unspecified units) for the roots, xylem, leaves and gaseous phase respectively.  $dm/dt$  can be equated to  $\frac{P_T V}{t}$  and

the equivalent partial pressures of aqueous vapour (atm) can be substituted for diffusion pressure deficits, with a change of sign.

We can then use equation (1) to calculate the resistance in the plant ( $R_r + R_x + R_l$ ) with potential difference ( $P_0 - P_3$ ) and that in the gas phase ( $R_g$ ) with ( $P_3 - P_4$ ). The ratio of these resistances is obviously  $(P_3 - P_4) \div (P_0 - P_3)$ ; in the example given by Dr. Levitt this ratio is 13 : 1, whereas for the osmotic potential differences the ratio was 20 : 1. The arbitrary choice of water vapour or liquid water as the basis for comparison thus leads to different values, showing that the method is at best very approximate. The difference arises from the logarithmic relation between osmotic pressure and equivalent vapour pressure; there is, at least, no doubt as to the part of the system with the greatest resistance.

In making these calculations it must be assumed that the environment provides a heat flow to the leaves at a rate just sufficient to maintain the system isothermal, with the production of  $P_T V/t \text{ cm}^3 \text{sec}^{-1}$  of water vapour.

Although van den Honert<sup>2</sup> reached a correct qualitative conclusion as to the relative magnitude of the resistance in the plant and gaseous phase, respectively, he did not state at all clearly the implications for the survival of the plant. He suggested that control of rate of water transport in the plant could only be effective in the gaseous phase, that is, reduction of stomatal aperture, and wrote: "If, for instance, the filtration resistance of the roots is increased, it will have little effect on the rate of water transport; its only effect will be an increase of diffusion pressure deficit in the whole plant". That would, however, depend on the absolute increases in resistance that could be achieved in the two phases, and if equation (2) could be accepted it is obvious that the same absolute increase in any of the resistances would have the same effect on steady state flow. If the resistance in either phase became infinite, water transport would, of course, come to an end. The important difference is that the main effect of resistances in the liquid phase, with the exception of that for the final path from the mesophyll cell to the intercellular space system of the leaf, is to restrict the replacement of the water lost by transpiration; resistances in the gaseous phase restrict that loss. Thus, the former may be considered "harmful" resistances and the latter "protective". A large increase of resistances in the liquid phase would reduce transpiration, but the leaves could be killed and desiccated before a steady state was reached.

Whether water movement through plants obeys the Ohm's law analogy must be tested experimentally by finding whether rate of flow is directly proportional to potential difference. There is some evidence that it is not<sup>3,4</sup>, and for such a heterogeneous and non-rigid system as a plant perhaps this is not surprising.

## PSYCHOLOGY

## Memory Enhancement by Anticholinesterase as a Function of Initial Learning

WHEN a well learned habit is clearly remembered its recall is blocked by an intracerebral injection of the anticholinesterase di-isopropyl fluorophosphate (DFP)<sup>1</sup>. When, however, the same habit is almost forgotten its memory is enhanced by treatment with the same drug<sup>2</sup>. Here we show that when a habit is only partially learned its recall is enhanced by injection of the anticholinesterase DFP, and further that the better the original learning of the habit the worse the recall of the habit after treatment with the drug.

Seventy-two male albino rats (Sprague Dawley, Holtzman strain, 400 g) were trained in a Y-maze to escape a shock by running to the lit arm of the maze as previously described<sup>1,2</sup>. The light in the correct arm was dim to make the task difficult. The rats were randomly assigned to one of six groups before initial training. The first two groups were given thirty trials of learning. The second two were given seventy trials, and the third two 110 trials. The first group of each pair was injected with the drug in the same manner and quantity as already described<sup>1,2</sup>, 5 days after initial learning. The second group of each pair was simply injected with the vehicle peanut oil, 5 days after training, again as previously described<sup>1,2</sup>. All groups were tested for recall of the habit 24 h after the injection. The difference between the number of correct choices during the last ten trials in original training and the number of correct choices during first ten trials of the post-injection test were used as an index of recall.

The three groups injected with peanut oil and trained to three different levels forgot approximately the same amount in terms of an increase in errors during the first trials of retraining (Table 1). On the other hand, the rats trained for only thirty trials and then injected with DFP showed a large and significant enhancement of recall when compared with their own performance in the last ten trials of initial training and the performance of the thirty trial control group in recall.

Table 1

Treatment of trials (DFP or peanut oil)	No. in initial learning	Learning score		Retention score		Difference score Retention - Learning	
		Mean	S.D.	Mean	S.D.	mean	S.D.
DFP	30	6.75	1.76	8.75	1.05	2.00	2.24
PO	30	8.00	2.08	6.75	1.48	-1.25	1.42
DFP	70	8.50	1.37	8.58	1.56	0.08	2.32
PO	70	8.25	1.48	7.92	1.18	-0.33	1.61
DFP	110	9.75	0.63	7.50	1.35	-2.25	0.90
PO	110	8.92	1.49	8.00	1.25	-0.92	2.02

Duncan's new multiple range test on difference scores

110 C	**	ns	ns	ns	ns	—

DFP, Di-isopropyl fluorophosphate; PO, peanut oil; C, control.

This enhancement of recall did not occur in the groups which had seventy or 110 trials when they were treated with DFP. Table 1 shows that the greater the number of initial trials of learning the greater the degree of forgetting after treatment with DFP and the smaller the amount of enhancement of recall with this drug. This trend is linear and statistically significant at the 0.01 level (analysis of variance). The difference in amount of forgetting displayed by the 110 trial DFP and control groups just misses significance.

An alternative test of the hypothesis in this investigation should show that there is more facilitation by DFP in animals which had learned less, and more impairment in those who had learned more within each group. Cor-

relations between learning and retention were computed within each group and the correlations were compared (Table 2). The difference in the thirty trial groups is significant and in the correct direction. In the seventy trial groups it is in the right direction. It is to be expected on purely mathematical grounds that the correlation between initial performance and retention should fall off as the initial performance approaches a perfect score for all the members of a group, because any difference in amount of initial learning cannot be mirrored by a difference in score. The present results show the same effect of facilitation as a pilot study using an easier discrimination task with 14-day-old memories.

Table 2. COMPARISON OF INTRAGROUP CORRELATIONS BETWEEN LEARNING AND RETENTION

	DFP	Control	Standard error	Z	P
30	-0.18	+0.70	0.47	2.23	<0.05
70	-0.23	+0.28	0.47	1.10	ns
110	+0.17	-0.05	0.47	0.60	ns

DFP as an anticholinesterase delays the destruction of acetylcholine. At low effective levels of acetylcholine synaptic transmission is facilitated, a fact used in the treatment of myasthenia gravis. With increasing quantities of acetylcholine facilitation turns into progressive synaptic block. The findings reported here are therefore interpreted<sup>3</sup> to show that during learning a set of synapses is stimulated to increase their capacity to emit transmitter, and that with increased learning of the same habit the capacity of these synapses is boosted further. Consequently, facilitation is seen with poorly learned habits, while progressive blocking of recall is observed with well learned habits, keeping dose of drugs and learning task constant.

## Effects of Neonatal Amygdalectomy in the Maternally Reared and Maternally Deprived Macaque

IN the monkey, bilateral amygdalectomy results in a number of behavioural changes which have been well documented<sup>1-4</sup>. These changes consist of (1) reduction in aggressiveness and relative tameness toward man; (2) increased orality, coprophagia and the mouthing of inedible objects; (3) hypermetamorphosis; and (4) hypersexuality. While these changes may be enhanced by extending the lesion to include the temporal neocortex and hippocampus, it has been established that these behavioural alterations can be produced by ablation of the amygdaloid nuclei alone<sup>2</sup>.

This lesion produces a profound alteration in adult behaviour and so it would be of interest to examine the development of animals subjected to similar ablations at various ages. In the kitten<sup>5,6</sup>, one of us (A. J. K.) found that lesions of the amygdaloid nuclei from 2-50 days of age did not result in the behavioural changes seen after similar ablations in the adult. Growth for the first year of life was unaffected as was the time of appearance of play and aggressive behaviour. This report will deal with the effects of amygdala lesions in the monkey produced during the first week of life (Fig. 1).

Monkeys reared in social isolation display marked fear reactions, lack of socialization and bizarre stereotyped motor behaviour<sup>7</sup>. One of the prominent effects of amygdectomy is a reduction in fear responses, and so it was of major interest in this investigation to observe the effects of this lesion on the maternal deprivation syndrome.

All monkeys used in this investigation were from the genus *Macaca*—four *M. mulatta*, three *M. speciosa* and one *M. radiata*. All neonates were born in the laboratory from imported pregnant females or from laboratory matings. Of the newborns, two were returned to their mothers after operation and two were reared artificially to examine the effects of this lesion on the maternal deprivation syndrome. Similarly there were two groups of juvenile operates, two which were maternally reared and two which were artificially reared and which displayed the deprivation syndrome at the time of operation. Data were collected about the growth of the neonates, infant-maternal interaction, visual exploratory behaviour, and, in the juveniles, quantitative measures of affective changes. All lesions were made by aspiration under direct exposure. Anaesthesia was accomplished with intraperitoneal pentobarbital sodium, 12 mg/lb. body weight. In the neonates, surgery was carried out within the first five post-natal days.

Post-surgically, the monkeys were given penicillin and subcutaneous fluids. They were kept in an incubator until the following morning when two were returned to their respective mothers and two were kept in the incubator and nursed by bottle with a synthetic milk preparation. The neonates were alert and vocal from 6 to 12 h after operation. Those that were returned to their mothers were readily accepted and oriented to the nipple almost immediately. The infants displayed good grasping and sucking, and remained on the nipple in the manner of normal neonates. In all gross respects they appeared to be unaffected by the operation. In time, the infants were observed to nibble at solid food, separate themselves for progressively longer periods and at greater distances from the mother, and to respond to strangers by quickly returning to the mother's breast. This is behaviour typical of the normal infant. No lethargy or hyperactivity was noted.

Those neonates who were maternally deprived were also alert and responsive after operation. They readily nursed from the bottle and learned to climb a module and to feed on their own after a short training period. They were nibbling solids at 4–6 weeks and were totally weaned to solid food without difficulty. By 3–4 weeks of age, two maternally deprived amygdectomized monkeys showed cowering, rocking, excessive non-nutritive sucking of thumbs and feet and general withdrawal. As they grew older they would withdraw at the approach of observers, cower and rock in a corner or hide under cover. This is characteristic for normal monkeys raised under similar conditions as has been well documented<sup>7</sup>. From

Fig. 2. Growth curves for eight infants from birth to 20 months. Each line represents two animals. ...., Amygdala lesioned, maternal deprivation; ----, amygdala lesioned, maternal reared; —, maternal deprivation; ———, maternal reared.

4 months to 1 yr the maternally reared amygdectomized monkeys remained active and alert and would nip when handled. In the rhesus, grimacing, withdrawal, piloerection, defecation, threatening postures and barking all occurred in response to the presence of observers as in the normal rhesus. There was no evidence of coprophagia, excessive mouthing, or sexual behaviour until the time of being killed at 1–2 years of age. While the *M. speciosa* juveniles were more docile than the rhesus, they likewise did not display evidence of the amygdala syndrome. Growth curves for eight females, four with amygdala lesions and four unoperated, are shown in Fig. 2. Two monkeys in each group were maternally deprived and two were mother-reared. No marked differences are seen for the first year of life, but there may be a tendency for the operates to show less weight gain after 1 yr. This group was killed before puberty, and so only the early growth phase can be demonstrated.

The marked reduction of fear responses in adult monkeys subjected to amygdectomy does not develop when the lesion is produced during the early post-natal period. Nor does it affect the marked fear and withdrawal which develop in the maternally deprived monkey. While some diminution of the deprivation syndrome occurred in a juvenile group, the subjects did not resemble the typical amygdectomized preparation (our work, in preparation). These results would suggest that (a) the effects of amygdectomy are age-dependent and may require some degree of sexual maturation before becoming manifest; (b) the lack of influence of amygdectomy on the maternal deprivation syndrome would indicate that this behaviour is mediated by sub-cortical structures, is fixed rather early in life, and is not grossly influenced by higher brain systems; and (c) growth for the first year of life and appropriate infant-maternal transactions are not grossly affected by neonatal amygdectomy.

## AGRICULTURE

### Influence of Algal Growth-promoting Substances on Growth, Yield and Protein Contents of Rice Plants

GERMINATION of paddy seeds is accelerated after treatments with algal hormones<sup>1,2,4</sup>. If rice seeds are treated with extracts of the *Phormidium* species before sowing, the algal hormone in the extract markedly promotes growth and development of both roots and shoots of rice seedlings<sup>3</sup>. The present investigation deals with the effect of algal hormones in extract of *Phormidium foveolarum* (Mont.) Gomont on vegetative growth, crop yield and protein content of rice seeds.

Seeds of paddy type 21 were pre-soaked for 24 h in 0.5, 1 and 5 per cent water and ether extract of *Phormidium foveolarum* suspended in water. Seeds soaked in distilled water served as a control. The method of hormone extraction and pre-soaking has been described in another communication (Gupta and Shukla, in the press). Immediately after soaking, seeds were sown in earthen pots filled with standardized garden soil. Four plants per pot were sown and raised to maturity. Observations were recorded fortnightly.

The beneficial effect was maintained throughout the duration of the crop.

Ether extract suspended in water also exercised a beneficial effect on vegetative growth of plants. The maximum increase in height of plants and length of leaves was observed in plants treated with 1 per cent algal extract, while number of leaves, breadth of leaves and numbers of tillers was markedly better in 5 per cent ether extract. The difference in 1 and 5 per cent treatment, however, was on the whole slight.

Observations on the dry weight of the plant (straw), total weight of all ears per plant, weight of a single ear and weight of 1,000 grains are recorded in Table 2. The data suggest that in the case of water extract the best results are obtained with 5 per cent while in ether extract suspended in water 1 per cent is most effective. The protein content of seeds was also increased in 1 per cent ether extract suspended in water and 5 per cent water extract.

The results indicate that the treatment with algal extract containing hormones exercises a marked beneficial effect on the growth and development of rice plants and the yield is increased significantly. Apart from the better yield the quality of the grains is also improved because they are richer in proteins (Table 3).

Table 3. EFFECT OF PRE-SOAKING SEEDS IN EXTRACTS OF *Phormidium foveolarum* ON PROTEIN CONTENT OF RICE PLANTS

Extract	Control		0.5 per cent		1 per cent		5 per cent	
	Total nitrogen (per cent)	Total protein (per cent)	Total nitrogen (per cent)	Total protein (per cent)	Total nitrogen (per cent)	Total protein (per cent)	Total nitrogen (per cent)	Total protein (per cent)
Ether suspended in water	1.75	10.93	1.61	10.05	1.81	11.31	1.5	9.75
Water extract	1.75	10.93	2.08	13.0	2.83	17.68	3.67	22.83

After harvesting the matured plants, the weight of straw, the weight of ears per plant, the average weight of a single ear and the weight of 1,000 seeds were recorded. Nitrogen contents of the seeds were estimated by Kjeldahl's standard micro method and their protein contents were calculated<sup>5</sup>.

Observations were made on all seeds which germinated within 96 h and the results from 14-22 replicates in various treatments were averaged. The results of the beneficial effect of concentrations of water extract and ether extract suspended in water are recorded in Table 1. The data show that the height of the plant, the number of tillers, the number of leaves, the length and the breadth of leaves increased considerably following treatment with 5 per cent water extract as compared with the control.

A comparison of treatments with 1 per cent ether extract suspended in water and 5 per cent water extract shows that both yield and protein content are very significantly increased in the treatment with 5 per cent water extract.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, February 20

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 9.30 a.m.—Colloquium on "Message Switching".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 2 p.m.—Colloquium on "Precision Resistance Standards".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. K. R. Sealey: "The Siting and Development of British Airports".

UNIVERSITY OF LONDON (in the Engineering Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. G. Kendall, F.R.S.: "Delphic Semi-Groups".\*

## Monday, February 20—Tuesday, February 21

INSTITUTION OF ELECTRICAL ENGINEERS (joint symposium with the I.C.E. and the I.Mech.E., at the Institution of Civil Engineers, Great George Street, London, S.W.1)—Symposium on "Area Control of Road Traffic".

## Tuesday, February 21

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.20 p.m.—Dr. D. J. B. White: "Blakeney Point (Norfolk) Nature Reserve".\*

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. M. J. Batkinson, Mrs. S. Day, Prof. N. Mullineux, Mr. K. C. Parton and Mr. J. R. Reed: "Calculation of Switching Phenomena in Power Systems"; Mr. J. P. Blekford and Mr. P. S. Doepel: "Calculation of Switching Transients with particular reference to Line Energisation".

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the I.Mech.E. and Society of Instrument Technology, at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. R. J. Redding and Mr. L. C. Towle: "Barrier Method of Ensuring the Safety of Electrical Circuits in Explosive Atmospheres".

PLASTICS INSTITUTE, LONDON SECTION (at the Kensington Close Hotel, Wright's Lane, London, W.8), at 5.30 p.m.—Mr. J. Morrish and Mr. J. E. Weaver: "Cost Accounting and the Fabricator".

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Dr. H. O. J. Collier: "Humoral Factors in Bronchial Constriction" (Twelfth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 6 p.m.—Prof. Paul Fraise (Paris): "The Speed of Perception". (Further lectures on February 22 and 24).\*

SOCIETY FOR ANALYTICAL CHEMISTRY, SPECIAL TECHNIQUES GROUP (in Lecture Theatre C, Chemistry Department, Imperial College, London, S.W.7), at 7 p.m.—Dr. D. W. Turner: "Molecular Photoelectron Spectroscopy and the Investigation of Molecular Orbital Energy Levels".

## Wednesday, February 22

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (joint meeting with the Food Group, at the School of Pharmacy, Brunswick Square, London, W.C.1), at 2.30 p.m.—Meeting on "The Effects on Microbiological Condition of Minor Ingredients in Foods".

ROYAL STATISTICAL SOCIETY (in the Gustave Tuck Lecture Theatre, University College London, Gower Street, London, W.C.1), at 5 p.m.—Prof. E. J. Williams (University of Melbourne): "The Analysis of Association among Many Variates".

MENTAL HEALTH RESEARCH FUND (at the Edward Lewis Theatre, Middlesex Hospital Medical School, Cleveland Street, London, W.1), at 5.30 p.m.—Dr. Heinz F. R. Prechtl (University of Groningen): "Neurological and Behavioural Sequelae of Pre- and Perinatal Brain Damage".

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Prof. N. M. Hancock: "The Cellular Basis of Bone Modelling". (First of three lectures on "The Scientific Basis of Dentistry" organized by the British Postgraduate Medical Federation).\*

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the I.E.R.E. Medical and Biological Electronics Group, at the I.E.R.E., 9 Bedford Square, London, W.C.1), at 6 p.m.—Meeting on "Electrodes for Long-Term Physiological Measurements".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, TELEVISION GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Mr. P. L. Mothersole, Mr. D. S. Hobbs and Mr. D. J. King: "A Dual Standard Colour Television Receiver".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. Maurice Goldsmith: "The Science of Science".

SOCIETY OF ENVIRONMENTAL ENGINEERS, PACKAGING GROUP (in the Department of Mechanical Engineering, Imperial College, Exhibition Road, London, S.W.7), at 6 p.m.—Discussion on "Desiccation—Are We Too Generous?" led by Mr. D. C. Allen.

## Thursday, February 23

BRITISH COMPUTER SOCIETY (at the City University, St. John Street, London, E.C.1)—Symposium on "Reduction of Costs in Distribution".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. C. J. Dean, Mr. P. Feldschreiber, Mr. L. D. G. Hamilton, Mr. J. T. Lett, Mr. J. G. Little and Miss Kathleen Steele: "The Repair of X-ray Damage to the Deoxyribonucleic Acid in *Micrococcus radiodurans*".

ASSOCIATION FOR SCIENCE EDUCATION (at Goldsmith's College, New Cross, London, S.E.14), at 5.15 p.m.—Meeting on "Experimental Closed Circuit Television in Science Teaching" introduced by Mr. T. Gibson.

INSTITUTION OF CIVIL ENGINEERS, HYDROLOGICAL GROUP (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Climatic Trends and their Hydrological Consequences" introduced by Mr. H. H. Lamb.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "The Manley-Rowe Relations" opened by Prof. J. Brown.

UNIVERSITY OF LONDON (at Senate House, London, W.C.1), at 5.30 p.m.—Prof. Sir Hans Krebs, F.R.S.: "Biological Concepts in Biology" (The John Coffin Memorial Lecture).\*

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Dr. A. E. R. Thomson: "Studies on Human Peripheral Blood Lymphocyte Populations". (Thirteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

UNIVERSITY OF LONDON (in the Engineering Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. G. Kendall, F.R.S.: "Renewal Sequences and Their Arithmetic".\*

## Friday, February 24

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W.1), at 1 p.m.—Mr. G. Shaw: "Photochemistry in Polymer Media".

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion on "Thermal Balance in the Ionosphere". Chairman: Prof. D. R. Bates, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. M. R. Harris and Mr. W. Z. Fam: "Analysis and Measurement of Radial Power Flow in Machine Airgaps".

UNIVERSITY OF LONDON (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. Charlotte Auerbach, F.R.S.: "Mutagenesis Research in Edinburgh. I, Delayed and Unstable Mutations".\*

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. C. A. Coulson, F.R.S.: "Science and Religion".

## Friday, February 24—Saturday, February 25

UNIVERSITY OF BRADFORD, POSTGRADUATE SCHOOL OF STUDIES IN POLYMER SCIENCE (at the University)—Symposium on "Structural Analysis of Polymers".

## Saturday, February 25

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. Adrian Digby: "Daily Life and History of the Aztecs".\*

## Monday, February 27

INSTITUTE OF ACTUARIES (in Staple Inn Hall, High Holborn, London, W.C.1), at 5 p.m.—Prof. G. A. Barnard: "The Bayesian Controversy in Statistical Inference".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. B. M. Weedy and Mr. J. P. Perkins: "Steady-State Thermal Analysis of a 400 kV-Cable Through Joint"; Dr. B. M. Weedy: "Thermal Aspects of Changes in the Environment of Underground Cables".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. R. Pollard: "Storage Systems for Telephone Switching".

UNIVERSITY OF LONDON (in the Engineering Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. G. Kendall, F.R.S.: "The Arithmetic of the Kingman Semi-Group".\*

UNIVERSITY OF LONDON (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. Charlotte Auerbach, F.R.S.: "Mutagenesis Research in Edinburgh. II, Mutagen Specificity".

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W.3), at 6.15 p.m.—Dr. R. Gold and Mr. M. Paneth: "Management of Pulmonary Embolism".\*

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Eccleston Hotel, London, S.W.1), at 7.30 p.m.—Meeting on "The Automotive Industry—Are Reinforced Plastics Making Progress?"

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (with two years experience in general pathology, including morbid anatomy) in FORENSIC MEDICINE—The Secretary, The London Hospital Medical College (University of London), Turner Street, London, E.1 (February 21).

ASSISTANT LECTURER (with an honours degree and qualified in formal logic) in PHILOSOPHY—The Registrar, University of Warwick, Coventry, Warwickshire (February 23).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS (below the age of 30 with a Ph.D. degree or equivalent research experience) in APPLIED MATHEMATICS, BIOLOGICAL SCIENCES, CHEMISTRY, ENGINEERING AND TECHNOLOGY, AND PHYSICS—The Academic Registrar, The City University, St. John Street, London, E.C.1 (February 24).

LECTURER in the DEPARTMENT OF INORGANIC CHEMISTRY—The Registrar, The University, Newcastle upon Tyne 2 (February 25).

LECTURER in the DEPARTMENT OF PHYSIOLOGY—The Secretary, The University, Aberdeen (February 25).

LECTURER or ASSISTANT LECTURER in the DEPARTMENT OF BIOCHEMISTRY—The Registrar, The University, Hull (February 25).

POSTDOCTORAL FELLOW in PHYSICAL CHEMISTRY—The Registrar, The University, Leeds, 2 (February 25).

POSTDOCTORAL FELLOW (Theoretical Physicist) to work on the electronic properties associated with dislocations in crystals—Dr. D. Pugh, Department of Pure and Applied Chemistry, University of Strathclyde, Glasgow, C.1 (February 25).

RESEARCH ASSISTANT in the SUB-DEPARTMENT OF COMPUTATION in the DEPARTMENT OF MATHEMATICS—The Registrar, The University, Hull (February 25).

ASSISTANT LECTURER in ORGANIC or INORGANIC CHEMISTRY—The Registrar, The University, Leicester (February 28).

LECTURER in LOGIC and METAPHYSICS in St. Salvator's College—The Secretary, University of St. Andrews, College Gate, St. Andrews, Fife, Scotland (February 28).

LECTURERS in both THEORETICAL AND EXPERIMENTAL PHYSICS—The Registrar, University of Warwick, Coventry, Warwickshire (February 28).

SENIOR LECTURER/LECTURER (preferably with postgraduate experience in the fields of entomology (other than taxonomy), mammalogy and wild life management and comparative physiology) in the DEPARTMENT OF ZOOLOGY, University of Ghana—The Assistant Registrar, Universities of Ghana Office, 15 Gordon Square, London, W.C.1; or The Registrar, University of Ghana, P.O. Box 25, Legon, Accra, Ghana (February 28).

POSTDOCTORAL RESEARCH FELLOW in the DEPARTMENT OF PHYSICS in the field of theoretical solid state physics, with particular reference to magnetooptical phenomena—The Deputy College Secretary, Westfield College (University of London), Kidderpore Avenue, Hampstead, London, N.W.3 (March 3).

SENIOR LECTURER IN VETERINARY PATHOLOGY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, March 3).

AGRICULTURIST (with a degree or diploma in agriculture) to organize field experiments using small plots—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1052/97 (March 4).

LECTURER/ASSISTANT LECTURER in BIOLOGICAL CHEMISTRY—The Secretary, The University, Aberdeen (March 4).

LECTURER in VETERINARY PATHOLOGY—The Secretary of the University Court, The University, Glasgow (March 4).

CHAIR OF PLANT PHYSIOLOGY—The Registrar, The University, Nottingham (March 6).

LIBRARIAN/MAP CURATOR (fully or partly qualified librarian with some experience or interest in map collections) in the DEPARTMENT OF GEOGRAPHY—The Secretary, The University, Southampton (March 6).

READER in MATHEMATICS at Royal Holloway College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 7).

ASSISTANT LECTURER or LECTURER (with particular interests in economic geology or in fields related to engineering geology) in APPLIED GEOLOGY—The Registrar, The University, Sheffield (March 10).

LECTURER in HEAT TRANSFER and FLUID DYNAMICS in the DEPARTMENT OF NUCLEAR ENGINEERING (applicants need not necessarily have a nuclear engineering background)—The Registrar, Queen Mary's College (University of London), Mile End Road, London, E.1 (March 10).

OFFICIAL TUTORIAL FELLOW in PURE MATHEMATICS—The Secretary, Balliol College, Oxford (March 11).

ASSISTANT LECTURER (preferably with research experience in physiology, experimental parasitology or behaviour) in ZOOLOGY—The Registrar, The University, Nottingham (March 13).

CHAIR OF BIOCHEMISTRY—The Staff Officer, University of Surrey, Battersea Park Road, London, S.W.11 (March 17).

PROFESSOR OF APPLIED OPTICS in the DEPARTMENT OF APPLIED PHYSICAL SCIENCES—The Registrar (Room 39, O.R.B.), The University, Reading (March 18).

LECTURER (man or woman graduate) in BOTANY—The Registrar, University Senate House, Bristol, 2 (March 20).

LECTURER or ASSISTANT LECTURER (with qualifications in comparative physiology) in ZOOLOGY—The Registrar, University College of North Wales, Bangor, North Wales (March 20).

LECTURER/SENIOR LECTURER in PARASITOLOGY at the University of New England, Armidale, New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, March 24).

READER (with research interests in any branch of chemical engineering, high academic qualifications and substantial research accomplishments) in CHEMICAL ENGINEERING—The Secretary, Royal College of Advanced Technology, Salford 5, Lancs, quoting Ref. CE/1 (March 27).

KEEPER (with an appropriate university degree and preferably museum experience) of ZOOLOGY—The Secretary, National Museum of Wales, Cardiff (March 29).

LECTURER or ASSISTANT LECTURER in INORGANIC CHEMISTRY; and a LECTURER or ASSISTANT LECTURER in PHYSICS at the University of Botswana, Lesotho and Swaziland—The Inter-University Council, 33 Bedford Place, London, W.C.1 (March 31).

LECTURER or ASSISTANT LECTURER in the DEPARTMENT OF ANIMAL GENETICS—The Secretary, University College London, Gower Street, London, W.C.1 (March 31).

PROFESSOR and HEAD of the DEPARTMENT OF BOTANY, Makerere University College, University of East Africa—The Inter-University Council, 33 Bedford Place, London, W.C.1 (March 31).

WAYNEFLETE PROFESSOR OF METAPHYSICAL PHILOSOPHY—The Registrar, University Registry, Oxford (April 8).

SEDLERIAN PROFESSOR OF NATURAL PHILOSOPHY—The Registrar, University Registry, Oxford (April 22).

ENTOMOLOGIST (national of the United Kingdom or Republic of Ireland, with a Bachelor's degree in biological sciences and some tropical experience, preferably on malaria) in the British Solomon Islands, to assist with the Malaria Eradication Project—The Ministry of Overseas Development, Room 403, Eland House, Stag Place, London, S.W.1.

LECTURER (with research interests in topics such as numerical analysis, mathematical statistics and probability, continuum mechanics) in APPLIED MATHEMATICS—The Registrar (Room 39, O.R.B.), The University, Reading, quoting Ref. AM.2.

MASTER to teach CHEMISTRY to Open Award standard—The Master, Dulwich College, London, S.E.21.

PRECISION  
ELECTRO  
MAGNETIC**stop** watches

for scientific and industrial use are supplied to industrial organizations and research establishments. Inquiries are welcomed.

**Our range of catalogues and leaflets covers:**

Watches, stop watches and chronographs; Recording apparatus; clocks, domestic and industrial. Process timers and time interval meters; Electrically controlled stop watches, tachometers, revolution and impulse counters. Any of these will be sent on request.

**REPAIR SERVICE**

One fiftieth-second Electro-Magnetic stop watch with electrical starting and stopping. Standard voltages 12-24 D.C., 200/250 A.C. Other types available with electrical reset to zero.

### APPOINTMENTS VACANT

UNIVERSITY OF  
STRATHCLYDE  
DEPARTMENT OF APPLIED  
MICROBIOLOGY AND BIOLOGY

#### SENIOR LECTURESHIP IN MICROBIOLOGY

Applications are invited for the above post. It is desirable that applicants have an interest in industrial aspects of the subject. The successful applicant will take part in undergraduate and postgraduate teaching and will be expected to contribute actively to the research programme in the Department.

Salary scale, £2,785 to £3,205 per annum with F.S.S.U. placing on scale depending on qualifications and experience.

Application forms and further particulars (quoting 15/67) can be obtained from the Registrar, University of Strathclyde, George Street, Glasgow, C.1, with whom applications should be lodged by February 21, 1967. (641)

#### UNIVERSITY OF KHARTOUM

Applications are invited for two posts of (i) Senior Lecturer or (ii) Lecturer in (a) Measurements and Control, and Unit Operations and (b) Process Equipment Design, and Unit Operations in Department of Chemical Engineering. Salary scales: (i) £5,240 by £5,100 to £5,2,800 per annum; (ii) £5,1,500 by £5,75 to £5,1,800 by £5,100 to £5,2,300 per annum. Entry point according to qualifications. Cost of living allowance approximately £5,180 per annum at present. Outfit allowance £5,50. Family allowances: wife, £5,60 per annum; first child, £5,90 per annum; second and third child, £5,30 per annum each (£5,1=£1 0s. 6d.). Passages for appointee and family on appointment, termination and annual leave. Superannuation Scheme. Appointment for five years with possibility of renewal. Partly furnished accommodation provided at rent of 10 per cent of basic salary. Low rate of income tax.

Detailed applications (eight copies), naming three referees by March 23, 1967, to Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1, from whom further particulars may be obtained. (653)

CHELSEA COLLEGE OF  
SCIENCE AND TECHNOLOGY  
(UNIVERSITY OF LONDON)  
DEPARTMENT OF HISTORY AND  
PHILOSOPHY OF SCIENCE

Applications are invited for the post of Lecturer or Assistant Lecturer in PHILOSOPHY OF MATHEMATICS to date from October 1, 1967. Candidates should have a strong mathematical background, and be able to initiate a research group in Mathematical Logic, Theory of Probability or Philosophy of Mathematics. Salary scale (including London Allowance) will be: Lecturer, £1,530 to £2,330 (bar) to £2,690 per annum; Assistant Lecturer, £1,165 to £1,600 per annum, placement on the scale depending upon qualifications and experience.

Further particulars and application forms (to be returned by March 15) obtainable from the Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3. Overseas candidates may apply directly, and should send curriculum vitae and the names of two academic referees. (721)

AUSTRALIAN ATOMIC ENERGY COMMISSION  
RESEARCH ESTABLISHMENT, LUCAS HEIGHTS, NEAR SYDNEY

## RADIATION PHYSICS

Applications are invited from physicists for positions within the Health Physics Section to direct and carry out research in the field of radiation physics.

### RADIATION PHYSICS

To study energy transfer processes associated with the interaction of ionizing radiations with matter. We are particularly interested in positive ion interactions; current projects include elastic collisions and their biological effects, the influence of linear energy transfer on thermoluminescence response and F centre production in alkali halides, and ionization and excitation processes in liquids and gases. A 3 MeV Van de Graaff is available for this work and a 100 keV positive ion accelerator is under construction. (Position R10.)

### RADIATION STANDARDS

To establish absolute standards of exposure in the high energy and low energy X-ray region and to carry out research into methods of absolute measurement of radiation dose. Methods to be evaluated, both theoretically and experimentally, include free air chambers (of conventional and novel design) cavity ionization chambers and calorimetry. (Position R14.)

Applicants must possess a Ph.D. or qualifications and scientific research experience which, taken together, are equivalent thereto, have demonstrated a capacity for independent research and have a breadth of scientific interest which extends beyond their original specialized training.

Salary, dependent upon qualifications and experience, will be within the following ranges:

RESEARCH SCIENTIST	\$5,071 (Aust.)—\$6,409 (Aust.)
SENIOR RESEARCH SCIENTIST	\$6,673 (Aust.)—\$7,729 (Aust.)
PRINCIPAL RESEARCH SCIENTIST	\$7,991 (Aust.)—\$9,209 (Aust.)

(Female rates are \$428 (Aust.) less than male rates quoted)

Application forms and further information may be obtained by writing to Mr. C. M. Gray The Atomic Energy Adviser, Office of the High Commissioner for Australia, Canberra House, 10-16 Maltravers Street, Strand, London, W.C.2. (834)

### AGRICULTURAL RESEARCH COUNCIL OF CENTRAL AFRICA

#### SENIOR RESEARCH ENTOMOLOGIST RESEARCH ENTOMOLOGIST

For research in Biological Control of Tsetse Flies by the Method of Sterile Male Release

An A.R.C.C.A. research group of five graduates with a strong supporting staff and good field facilities has been working for the past three years, together with a team seconded from the U.S.D.A., on the field and laboratory development of this new technique. Both chemosterilant and radiosterilant treatments have been successfully proved and the project is at the Pilot Scheme stage on an island at Lake Kariba. There will shortly be a vacancy for an experienced research glossinologist in this group. Salary in the Principle Research Officer scale £2,136 to £3,000 according to qualifications and experience. An appointment may be offered in a higher scale for candidates of exceptional accomplishments. A three-year contract is offered with family return fares and mid-tour leave to Cape Town. A secondment for a shorter period of not less than a year would be considered. The post is available from March 1, 1967.

A vacancy will also occur for a newly qualified research entomologist to join this team at M.Sc. or Ph.D. level.

There are no application forms, but career details and the names of three referees should be sent to one of the undermentioned addresses:

The Secretary, Agricultural Research Council of Central Africa,  
P.O. Box 3397, Salisbury, Rhodesia.

P.O. Box 215,  
Lilongwe, Malawi.

P.O. Box 2218,  
Lusaka, Zambia.

# Imagine a Picogram

A picogram ( $1 \times 10^{-12}$  gm) cannot be weighed even by the most accurate balance and is barely visible through the most powerful microscope—yet fast, reliable measurements at picogram level can be achieved with an electron capture detector. Now available in Pye Series 104 Gas Chromatographs, this detector was originally developed for specialised work on steroids and pesticides but is rapidly proving its

value in other fields for research and routine analysis.

The Pye electron capture detector has a Nickel 63 source for operation to  $350^{\circ}\text{C}$ —this is unusual. Like all Pye detectors it is robust and reliable and has been thoroughly evaluated (see COLUMN\* vol 1, no 3).

The gas chromatographs which include this detector are Pye Series 104 Models 74 and 84. Please send for details.

\*At your request our gas chromatography bulletin, *Column*, will be mailed to you regularly

# DM23

**...newest addition  
to the famous  
Meopta range...**

The Meopta DM 23 offers working distance up to 200mm... and is typical of the superb workmanship, the reliability and the versatility for which the Meopta D range have justly become famous. The DM 23 can be supplied with a wide range of interchangeable parts—and full technical details will be supplied on request.

## ***Photo-electric Polarimeter***

A Photo-electric version of the popular Model A Polarimeter is now in production, providing much improved sensitivity ( $0.002^\circ$ ), and far less operator fatigue experienced on repetition work.

A major consideration in the design has been to provide absolute reliability in operation and trouble free service. The instrument is suitable for use in the Ultra-violet down to 230 mμ. with suitable monochromatic sources.

**The Polarimeter will be demonstrated on Stand E.11 at LABEX Exhibition at Earls Court, 13th-17th March, 1967.**

## NEW BROOM, SWEEP CLEAN

THE address by Professor P. M. S. Blackett to the Parliamentary and Scientific Committee was a courageous exercise. It is not every day that a distinguished public servant says in public what he really thinks. It is true that Professor Blackett is President of the Royal Society as well as the chief adviser at the Ministry of Technology, but even holders of that powerful office have usually chosen to "work behind the scenes" as the saying goes. If Professor Blackett goes on like this, he may easily persuade others who give advice to governments without becoming civil servants that they do not ever afterwards have to bite off their tongues, which would help enormously to improve the quality of public life. And he will find that for every Christmas card list from which he disappears, there are a dozen people willing to listen to old arguments for the first time. One of the delicate ironies of his address last week is that it will have won him (and the minister to whom he gives advice) friends and admirers in circles ordinarily moved by the deepest suspicion of what he is about.

What Professor Blackett had to say about the mergers of industrial enterprises is of course a central part of the new doctrine of the Ministry of Technology. The chief interest in what he had to say last week, however, is the seemingly innocent confession that the British Government may have "taken the wrong road" immediately after the war by putting too high a proportion of its research and development work with government establishments specifically set up for the purpose. It would have been better, the argument goes, if British industry had been more intimately involved. For one thing, manufacturing industry would have been given more direct experience—much of it undoubtedly painful—of creative innovation. For another, there would now have been a better distribution of the technically skilled labour force, with more people in industrial positions where they can contribute directly to the health of the British economy. Certainly, the skilled labour force would now have been more flexible. But if there have been mistakes, it may not be too late to put them right. The inference from what Professor Blackett has been saying is that the Ministry of Technology will now be doing everything it can to rectify an unbalanced situation, and to transfer more people and more work to industry. To begin with, of course, the ministry may find that it is itself its own worst enemy, for there are still many who think that it is possible to run an industry from an office. But, in the long run, it will find that the policy towards which it is now moving is not merely sensible but successful.

With industrial research, in any case, diagnosis may well turn out to be easier than cure. The trouble is

not that the government establishments have grown too big, but that they have grown into institutions. According to the most recent triennial survey of the employment of scientists and technologists, government agencies employed 32,000 qualified scientists and engineers in 1965, or just about one-seventh of those actively at work in Britain. The skilled labour force in government employ is more than a quarter of that at work in industry, although the proportion is declining slowly. The proportion is very much the same in Britain as in the United States, where 14 per cent of all qualified people were working for governmental organizations in 1964. In the circumstances, it would obviously be wrong if the British Government now promptly set out to sack a substantial number of the scientists and engineers on its payroll. It is true that there should be a much more easy flow of talent from the government establishments to industry and the universities—and in the other direction as well—but what really needs to be accomplished is a change in the conception of how a government should seek to stimulate industrial innovation. In the past two decades, there has been a tendency in Britain to believe that it is at once cheaper and more effective to carry out research and development centrally, for this tends to eliminate duplication and to concentrate ability in one team. The difficulty, of course, is that of making sure that research and development of this kind is sufficiently in touch with economic reality. In any case, research and development is not an end in itself, but often a means by which industrial companies learn to make full use of new techniques. In the circumstances, it will be entirely welcome if the British Government now resolves to carry out more research and development by letting contracts to laboratories outside its own organization. It is easy enough to imagine that by holding out some promise that this may happen, Professor Blackett will have made himself some unexpected friends.

How, then, should the British Government decide to place its money? Obviously the Civil Service must continue to shoulder a great part of the responsibility of deciding what kinds of developments should be encouraged. The government has done something to help in this direction by setting up planning groups at Harwell and Malvern, but there is obviously much more that can be done. It is also worth asking whether some government laboratories which at present exist to provide services to industry might not now be happier if they were autonomous organizations able to act more quickly than is at present easy. There remains the problem of how the Government can best stimulate industrial improvement. Professor Blackett is strong on the importance of the structure of industry, and

right to point to the anomalies which spring from the great fragmentation of many industries. But simply to arrange for mergers will not guarantee a cure. In exactly the same way, research and development by itself is not a sufficient condition for industrial prosperity. It is also necessary to arrange that industry has some attainable goal towards which to work. In fostering the development of computers, for example, the British Government would be well advised to spend at least as much energy (and possibly more money) on the encouragement of use as on the development of innovation. And the best way of bringing about mergers is to arrange that the economy should become thoroughly competitive. In other words, the economists have as much to say about technological improvement as have the technologists themselves. If this is how the Ministry of Technology is thinking, everybody will be delighted.

## MONEY FOR RESEARCH COUNCILS

THE Council for Scientific Policy seems to have won a fair settlement from the British Government over the budgets for the research councils in the financial year immediately ahead (see page 749). Less than a year ago, when the council produced its first annual report, there were some grounds for fearing that the spending of the councils would be kept on a much tighter rein. The possibility was real that the research councils might be kept on such short commons that they would be unable to take on new projects. Since then the economic situation has not improved, to say the best of it. In the circumstances an increase of 9 per cent in the aggregate budget of the four research councils operating in the natural sciences is as much as could reasonably have been expected. It is true that much of the extra money will be eaten up by the steadily increasing cost of keeping skilled men efficiently at work, and the Science Research Council will be particularly hard pressed by the welcome growth of the postgraduate population at the universities. But there should be something left over with which to break new ground. That is something to be grateful for.

There remains the problem of next year—and the one after. Will the Government be willing to underwrite the steady growth of the research councils which circumstances appear to make necessary? And are the research councils properly organized to do what is now expected of them? There is certainly a case for asking whether the medical and agricultural councils are right in spending a substantial part of their income on the direct support of research units and groups. More grant giving might give them more flexibility. And what should be the relationship between the research councils and the University Grants Committee? There is much to be said for Lord Bowden's argument that the research councils should be thought of as permanent supporters of university research, not merely as sponsors of new projects. But that

implies still faster growth. In other words, there are plenty of questions to occupy the Council for Scientific Policy in the year ahead.

## DR. ROBERT OPPENHEIMER

It is sad but also inevitable that Dr. Robert Oppenheimer should have acquired the public reputation of the first designer of nuclear weapons. What went on at Los Alamos during the last war was too important to be forgotten. One of Oppenheimer's most remarkable achievements is that he was able to make bombs and still seem to remain on the side of the angels. In the years immediately after the war, he was well served by the way in which the respect and admiration of his colleagues, and indeed of the whole profession of physics, were somehow translated into public esteem. It is also remarkable that he survived so well the inquiry into the granting of his security clearance to work as a consultant for the U.S. Atomic Energy Commission. The inquiry may have been a public scandal, and a malign attempt on the reputation of a distinguished man, but it was also damaging. In the eyes of all but a handful of fanatics, Oppenheimer was acquitted of the serious but implicit charge of disloyalty, which is only right and proper. But he emerged from the inquiry a little more like ordinary mortals, with feet of clay. What did he really tell the security men about Chevallier? And was he right to accept security restrictions for others but not himself? These remain absorbing questions. It is a tribute to him that they never seriously diminished the regard in which he was held.

With Oppenheimer dead, however, it is a pity that these cloudy issues must for many people conceal what must in retrospect be his greatest achievement. His reputation among his colleagues rests not on weapons nor on quasi-judicial inquiries, but on the way in which, almost single-handed, he carried the quantum theory to the United States. In this esoteric field he was a kind of St. Augustine. In the early thirties, he gave his contemporaries and their students an opportunity to swim quickly with the new tide then sweeping through Europe. By his art as a teacher, he made them see how important the consequences would be. In doing so, he helped to lay the foundations for a community of physics in the United States which is one of the intellectual attainments of this past few decades. Oppenheimer himself may not have done the most spectacular work, but his collaborators and students were scattered everywhere. If he had been less modest, he could have claimed to have had a hand in most of what was done in the thirties to make nuclear physics intelligible. But Oppenheimer was more than just a physicist. He had a flair for seeing wider issues. He was a great talker, with a gift for putting things well. After the hearings on his security clearance, he sometimes seemed to be a remote and even lonely figure, yet he somehow retained a flair for seeming young. That is yet another reason why he will be acutely missed.

# NEWS AND VIEWS

## British Science Spending

THE threatened squeeze on the research councils, which seemed all too imminent only a few months ago, has been postponed for at least another year. According to the preliminary estimates for expenditure by the British Government in the financial year 1967-68 (*Vote on Account 1967-68*, Cmnd. 337, H.M.S.O., 2s. 3d.), the allocation to the four principal research councils will increase by 9.6 per cent to a total of £68.3 million. Understandably, there is a still sharper increase of the budget of the newly formed Social Science Research Council from £709,000 to £1,162,000. On the face of things, it may therefore seem that the research councils are doing as well as can be expected at a time of financial stringency, and they seem to be well pleased with the way that things have turned out, even though they have recently been used to an even faster rate of growth—an increase of 20 per cent between 1965-66 and 1966-67, for example. The budgets of some of the councils may be more elastic than those of others, so that some councils may be less well placed to undertake projects in the year ahead. The allocations to the four research councils dealing with the natural sciences in recent years, in millions of pounds, are as follows:

	1965-66	1966-67	1967-68
Science Research Council	28.6	33.9	36.6
National Engineering Research Council	3.5	6.2	7.7
Medical Research Council	10.3	11.9	12.0
Agricultural Research Council	9.3	10.3	12.0
Total	51.7	62.3	68.3

The cost of research and development carried out within the budget of the Ministry of Defence will be marginally less during the coming financial year than in 1966-67. According to the *Defence Estimates* published last week (Cmnd. 312, H.M.S.O., 19s.), the total cost of defence research and development in 1967-68 will amount to £260 million, compared with £275 million in the previous financial year. Much of the decrease is accounted for by reduced expenditure on aircraft research and development.

## The Size of Technology

THE merging of the Ministry of Aviation with the Ministry of Technology on February 15 will have seemed much like a gnat swallowing an elephant. The entire cost of running the research and development establishments under the old Ministry of Technology was about £11 million, but those it has now acquired cost roughly £45 million a year to run (*Civil Estimates 1966-67*). But the Ministry of Technology is now also responsible for the expenditure of the Ministry of Aviation on industrial research and development, which cost £194 million last year, and support for the European Launcher Development Organization (ELDO), which cost £11.3 million. To round off Mr. Wedgwood Benn's new empire, there are the United Kingdom Atomic Energy Authority, whose civil activities cost £28.7 million in 1966-67, the National Research and Development Council, and the 8 research associations and the National Computing

### RESEARCH EXPENDITURE

	Expenditure (£)	
	Staff (salaries, etc.)	Capital and re-current expenses
Ministry of Technology		
Building Research Station	983,000	277,000
Fire Research Station	199,000	63,000
Forest Products Research Station	247,000	43,200
Hydraulics Research Station	281,000	95,200
Government Chemist Laboratory	591,000	86,200
National Engineering Laboratory	1,038,000	1,465,000
National Physical Laboratory	2,341,000	1,339,000
Torry Research Station	241,000	121,800
Warren Spring Laboratory	539,000	272,000
Water Pollution Research Laboratory	246,000	72,600
National Research Development Corp.		£7,400,000
U.K.A.E.A.		£28,723,000
Research Association grants		£3,570,000
National Computing Centre		£300,000
Ministry of Aviation		
Aeroplane and Armament Exptl. Est.	}	£44,830,000
Explosives R and D Establishment		
National Gas Turbine Establishment		
Rocket Propulsion Establishment		
Royal Aircraft Establishment		
Royal Radar Establishment		
Signals Research and D Est.		
U.K.A.E.A.		£54,900,000

Centre which cost £3.6 million and £0.3 million a year respectively.

Not all the new establishments seem to fit easily into the Ministry of Technology. It is difficult to see, for example, how it will use the Explosives Research and Development Establishment, or the Aeroplane and Armament Experimental Establishment. It might have been more consistent with the Ministry's pre-occupation if these establishments had been hived off to the Ministry of Defence. They will, in fact, be controlled from the building of the Ministry of Defence, since Mr. John Stonehouse, looking after the new acquisitions as

Old Ministry of Technology,  
total £51.35 million

New Ministry of Technology,  
total £344.5 million

- Research Associations
- N.R.D.C.
- Research Establishments
- U.K.A.E.A.
- Industry

\*This allocation includes the payment at present made by the Ministry of Aviation for special materials.

Minister of State at the Ministry of Technology, will have his office there.

The Ministry of Technology is to be organized in three main groups—Engineering, Research, and Aviation. The new controllers will be Dr. G. G. Macfarlane (Research) and Mr. Ieuan Maddock (Industrial Technology) (*Nature*, **213**, 645; 1967), while the Aviation section—the largest of the three—will be controlled by Air Marshal Sir Christopher Hartley.

## Profession of Physics

AN even more detailed analysis of the structure of professional physics has now been published by the American Institute of Physics, based in part on the information obtained from the National Register (*Physics Manpower 1966*, American Institute of Physics, \$2.50). The survey is particularly informative on the recruitment of physicists at different parts of the education system, and on the immigration into the United States of physicists from elsewhere.

The survey suggests that it is as yet too soon to know what the effect will be of the new physics courses produced by the Physical Science Study Committee on education in physics in the United States. Of those graduating in physics in 1966, only 16 per cent will have followed the PSSC course at high school. In future years, however, the crop should be larger, for it is estimated that in the academic year 1964–65, roughly 50 per cent of high school physics students in the United States were enrolled in a PSSC course. The survey points out that the numbers of physics teachers in high schools have been declining as a fraction of science teachers as a whole, which seems to imply an increase in the numbers of mathematicians and others on high school faculties. In the universities, the Institute of Physics has found that from year to year a smaller fraction of those who enrol for a degree elect to become physics majors at the end of their course. In fact, just over 1 per cent of male entrants to American universities in September 1962 chose to specialize in physics in September 1965, with universities on the north-eastern seaboard producing more physics students than their share.

Allowing for the relatively high rate of drop-out between one year and the next, it is estimated that the number of bachelor degrees in physics will decline from 5,500 or so at present to 4,500 or so by the end of the decade. But, because of the steadily increasing tendency for graduates to stay on for postgraduate work, it is expected that the output of higher graduates will gradually increase at least until the 1970s. In practice, just about a half of those graduating in physics seem to stay on for further study. The number of Ph.D. degrees awarded each year in the United States has increased from roughly 490 in 1955–56 to 983 in 1964–65. By the early seventies there are expected to be about 1,200 Ph.D. graduates each year.

On immigration into the United States, the report points out that roughly 12 per cent (1,800) of physics graduate students in the United States come from abroad and that 69 per cent (1,280) of these foreign students are from Asia. In 1964–65 Europe contributed 211 graduate students in physics to the total. On the employment in the United States of physicists with degrees from foreign universities, it appears that Europe contributes 72 per cent of the total of 1,315 at

work in 1964. The United Kingdom contributed 362 of these, West Germany 258, and Canada 137.

## R & D at the R.I.

“THE richest of all Lords is use” according to Emerson, and Lord Rothschild might have taken this as his text for his Friday evening discourse at the Royal Institution on February 17. His theme, “Research in a Very Big Industry”, gave him an opportunity to emphasize the virtues of the operations of monopoly corporations at the frontiers of knowledge, and to comment on the differences between academic and industrial research. Industrial research is more concerned with getting exploitable results than is the academic variety, and its results should ideally have some value and be available when they are wanted. Lord Rothschild felt that these questions are still too far in the background in much academic research. He had, he said, come across cases where work had been going on for years and years without anyone bothering to ask “Is it useful?”. The excuse given for this type of work, that it adds to the sum total of human knowledge, was “trite and inadequate”. So far as industry was concerned, it was as well to be wary in assessing the value of research to a company. In general, research does help growth, but the difficulty is to know whether companies with high growth rates favour research because they have a high growth rate or whether it is the research that produces the high growth rate.

## False Teeth in Space

THE view that “Mankind takes his dental problems with him wherever he goes” was the theme of the paper read by B. Lawrence Shalit to the conference on “Planetology and Space Mission Planning” held in New York at the end of 1965, the proceedings of which have now been published by the New York Academy of Sciences (*Annals*, **140**, Art. 1, 1; 1966). Although most of the contributions to the symposium dealt with the potential accomplishments of various rocket systems and the desirability of space missions such as landing on asteroids, Mr. Shalit put forward his plan for dental care in space “to prevent the astronauts from being incapacitated by dental problems and, secondarily, to protect the oral cavity of the individual astronaut from permanent damage of any type during space flight”.

At least for short flights, Mr. Shalit believes that it will be possible to correct most dental defects before launching, so that none of the common dental troubles need disqualify people from becoming astronauts. Moreover, Mr. Shalit rejects the notion that it would be simplest “to equip all astronauts with full dentures”; not merely would this make mastication less efficient but “the loss would be psychologically upsetting or even unacceptable”. He does, however, recommend that before sending men into space, dental surgeons should eliminate non-vital and suspicious teeth, third molars “if, in the opinion of the examiners, this is indicated”, the instruction of astronauts in the use of temporary fillings and analgesics, and the careful planning of meals so that starchy items are eaten first. On longer space flights, Mr. Shalit suggests that the potential hazards of dental caries should be minimized by “reduction in frequency of eating”, and that astro

nauts should be trained in scaling teeth. Mr. Shalit does not, however, consider that they should be trained to extract teeth because that "requires considerable clinical experience".

## Sponsored Research

by our Special Correspondent, Newcastle upon Tyne

IN the first flush of enthusiasm for nuclear power about ten years ago, C. A. Parsons and Co. set up a large research centre here to handle the development of nuclear engineering and materials. When hopes of a rapid expansion in nuclear power receded, the laboratory began to diversify and in 1962 it became International Research and Development Co., Ltd.—the largest establishment carrying out sponsored research in the United Kingdom. The company gives the impression of having had to struggle to maintain the heady optimism of the early nuclear days, but now seems to have overcome the danger of redundancy among staff and under-use of its ample facilities.

Starting IRD almost looks accidental; running it does not. The managing director is Dr. H. M. Finniston, and the research manager is Dr. H. Rose. Both have strong nerves, and need them. As Dr. Rose explains, "The company has no budget. We need more than £1 million a year to keep operating, but never know where it will come from". In fact about 75 per cent comes from industry, the rest mainly from defence contracts; only about 10 per cent of the work now has a nuclear slant. The company employs about 500, of whom 200 are professional staff, mostly graduates.

The activities of IRD are wide ranging. A great deal of effort is going into a long-term project of magneto-plasma-dynamic (MPD) power generation, which involves passing a stream of hot helium seeded with caesium through a magnetic field, thus generating electric power directly. IRD is working with a closed cycle system and the design calls for a nuclear reactor to heat the gas to about 2,000° C. An important objective is the study of the phenomenon of magnetically induced ionization which could have the effect of raising the electron temperature in the plasma without requiring such a high gas temperature. One of the long-term attractions of the closed cycle MPD system is its potential independence of fossil fuels. Elsewhere in Britain, the Central Electricity Generating Board is at present spending £2 million over three years on an open cycle MPD system at Marchwood. IRD has yet to find a sponsor for the future of its project, which will cost between £50,000 and £100,000 a year.

IRD is quite open about projects such as MPD, which are far from being commercial propositions. About some others, the company is more guarded, either for commercial reasons or because the sponsors are security conscious. In the engineering department work has been carried out on cryogenics, superconducting magnets and motors, and a new kind of homopolar machine. Here there is little direct information, but a barely suppressed sense of excitement. The applied sciences department uses lasers and low temperature engineering in a number of applications. There is a large chemistry department, working on studies of corrosion and on chemical processes. In the materials technology section, explosive treatment of metals has been studied; in addition to explosive forming, now

well known, welding treatments have been developed which may have important commercial applications.

IRD is interesting not only for what it does, but also for what it represents. If the Ministry of Technology contrives to diversify its laboratories, they may well be much like this. The idea is attractive, but Dr. Rose sees dangers if it is carried too far. He fears that in a laboratory controlled by the Civil Service, industry may be brought in too late on important projects, and the effect will be to double the amount of money spent. Diversified government laboratories, of course, may attract funds which would otherwise find their way to IRD, but this is not a field in which Britain is embarrassed by riches; there should be enough at least for the best projects in each laboratory.

## Weather Prediction

BRITISH meteorologists are delighted at the success with which Mr. F. H. Bushby and Miss Margaret Timpson of the Meteorological Office at Bracknell have been able to forecast rainfall by computer. The essence of what they have been doing was embodied in a paper read to the Royal Meteorological Society on February 15 and soon to be printed in the society's *Quarterly Journal*. Briefly, they have used a three-dimensional model of the atmosphere in which the possibility of precipitation is adequately taken account of. Numerical integration of the equations representing the model atmosphere has been carried out over a three-dimensional grid of points, with those at ground level separated by 40 km. Thus the physical scale of the weather forecasts obtained is comparable with that of the frontal systems with which precipitation is usually associated. Most of the numerical forecasting systems already in use depend on an integration network whose dimensions are more nearly comparable with the scale of large-scale phenomena such as anticyclones and the like. This system of equations has been used to produce a number of 24 hour forecasts for the British Isles and north-west Europe. A full integration takes 8 hours on the Atlas computer at the Chilton Computer Laboratory of the Science Research Council, which means that the meteorologists will now join the queue of those who would like to see the early coming of still faster computers.

The success of the few 24 hour forecasts so far produced has been impressive. In the prediction of the movement of a small wave depression across the south of Britain on December 1, 1961, for example, the progressive deepening of the depression was forecast, although the numerical value of the lowest pressure was 3 mbar too high after 12 hours and 3 mbar too low after 24 hours. At least a part of these discrepancies seems to be accounted for by large scale oscillations in the atmosphere with a time period of several hours, but fortunately their amplitude does not increase with time. One of the particularly cheerful features of the work is that an initially smooth network of observations can yield a sharp frontal system with the passage of time. Forecasts of actual rainfall agreed well with reality, although the axis of the predicted belt of rainfall was farther north than it should have been. Because the model does not, as yet, include the effects of convection, some thunderstorms were missed. It is acknowledged that the consequences of friction and topography are not included in the atmo-

spheric model, which means that rainfall may not be fully accounted for in the work so far carried out. None of this, however, has prevented meteorologists long trained to keep a quizzical eye on proposals for numerical forecasting from saying that the Bushby and Timpson article is a milestone in numerical forecasting.

## Traffic Delay Banished

SCHEMES for controlling the movement of traffic within large parts of urban communities were discussed at a joint symposium of the Institutions of Mechanical, Civil and Electrical Engineers on February 21 and 22. There seems to be great and widespread enthusiasm for area traffic control systems, but not yet enough experience for engineers to know precisely what the benefits will be. This, however, does not prevent people making forward estimates. Those in charge of the computer-controlled traffic light system now being installed in west London expect, for example, that the social benefit of their scheme will amount to more than £4.5 million in the coming decade. This estimate is based on calculation that the average annual value of delay at a traffic signal stop line is £10,500. The capital cost of the equipment now installed is £550,000. The calculation is that reduction in delay at stop lines of a mere 2 per cent will provide an 8 per cent return on the investment in control equipment, and that a 5 per cent reduction in delay will be equivalent to an annual interest payment of 19.1 per cent.

But how is it possible to be sure that computer control will reduce delay and not aggravate it? Various traffic control experiments, in Glasgow and Toronto as well as in several other cities, seem to differ considerably in the principles on which control is carried out. In the west London experiment, the state of traffic throughout the experimental area will be recorded by counts of vehicles on all the arms of signalled intersections, records of the development of queues at intersections, and the measurement of the speed of vehicles at several points within the system. The object of the control system will be to minimize the integrated delay experienced by vehicles. The computer system will be provided with a library of control patterns theoretically designed to increase what is called the progression of traffic within the area, and appropriate items from these will be selected at intervals of ten minutes or so by the control computer. No doubt it will be some time yet before there is enough experience of these different systems to know what criteria are most important in deciding between the many possibilities.

## Polymorphism in Transfer RNA

by a correspondent in Molecular Biology

THE determination of the base sequences of a number of transfer RNAs, and the apparent presence in them of extensive common features, poses the problem of how these analogies are reflected in the tertiary structure of the molecule, and indeed whether it can be said to possess a tertiary structure in the same sense as an enzyme. Results which bear on this problem have recently been reported from the laboratories of Fresco and of Sueoka. This month Fresco and his associates

(Lindahl *et al.*, *Proc. U.S. Nat. Acad. Sci.*, **57**, 178; 1967) describe further attempts to define the active and inactive states of transfer RNA. These are forms differing somewhat in their physical properties—in respect of partition coefficients in countercurrent distribution systems, for example, and in hydrodynamic characteristics, which can be rapidly interconverted by heating with magnesium ions (inactive to active) or with a chelating agent (active to inactive).

Many of the experiments which are described have been performed on three specific transfer RNAs, but the most extensive studies are on leucine-accepting tRNA from yeast. In the first place it is shown conclusively that only the active or "native" form will accept its amino-acid on incubation with the relevant synthetase. Secondly, the leucyl-tRNA charged with its amino-acid can likewise exist in the same two conditions, and it is shown that only the native form is a substrate for enzymatic removal of the leucine. The question then arises of whether the transfer enzyme recognition site on the RNA has been destroyed in the "denatured" form, or whether the enzyme recognizes the RNA but cannot operate on it as a substrate. This question has been partly answered by the use of an oxidized tRNA, in which the terminal sugar has been eliminated, and which is therefore incapable of binding an amino-acid. Such a molecule evidently retains its normal conformation, for it is capable of interacting with the enzyme, and is thus a powerful specific inhibitor. It is found that whereas both the native and denatured forms of this oxidized RNA inhibit considerably, the former has a greater effect. It thus appears that the enzyme-recognition site remains partly intact in the denatured form, but that the enzyme can nevertheless not operate on such a conformation.

A quite different enzyme for which transfer RNA (irrespective in this case of its amino-acid specificity) is a specific substrate, is adenylyl transferase, which is responsible for the incorporation of the terminal adenylic acid residue into the molecule. It is shown that here again the native conformation is strongly preferred. Finally, it has been demonstrated that only the native leucyl-tRNA will function to any significant extent in a cell free protein synthesizing system from *E. coli*. It appears, moreover, to have been established that this effect does not arise from the formation in the denatured form of a new functional anticodon pertaining to some other coding triplet than that for leucine.

This work appears to leave little doubt that transfer RNA is not a "shapeless" molecule which will take up its correct conformation only in the presence of a relevant enzyme. It points rather to the conclusion that the molecule, like a globular enzyme, can assume several conformations, one of which is preferable by a relatively small margin of free energy. This raises in turn the interesting question whether the conformational polymorphism of tRNA is related to the multiple requirements of its function. It is interesting to note in this connexion the report by Kuriki and Kaji (*Biochem. Biophys. Res. Commun.*, **26**, 95; 1967) that discharged phenylalanine-tRNA, which has been prepared by recovery from polyphenylalanyl-tRNA under mild conditions, will not accept phenylalanine. Therefore the polypeptidyl-tRNA is either chemically more labile than the free RNA or, more probably, the latter

has been recovered in a conformationally inactive state, which it would be satisfactory to identify with the "denatured" form of Fresco and co-workers.

## Parliament in Britain

THE House of Commons caused something of a stir on February 13 by putting the words "brain drain" on to an order paper which has usually been free from such popular excesses. In the event, Mr. Quintin Hogg set out to reprove the government for pursuing policies which have aggravated the emigration of skilled people from Britain. In his diagnosis of the causes of emigration, Mr. Hogg said that the sheer excellence of the British education system "makes us more vulnerable to the brain drain", but this was not a part of his complaint against the government. Rather, he was cross that "the society of the richest country in the world has been plundering the educational systems of Western Europe". But, that said, Mr. Hogg was against the restriction of movement among scientists, and opposed to the opting out of areas of research in which people are particularly vulnerable to emigration. Instead, he wanted to see a stronger European base for scientific work in Britain, more collaboration on European projects such as the Concord aircraft, a counter-recruitment drive and less fierce taxes.

The case for the government was put by the Minister of Technology, Mr. Anthony Wedgwood Benn, and by the Secretary of State for Education and Science, Mr. Anthony Crosland. Both of them were quick to point out that public expenditure on research and development has been increasing steadily. Mr. Benn said that steps are being taken to collect better statistics, that the group under Dr. F. E. Jones would be reporting on the brain drain in May this year, that there is a possibility of keeping a register of British scientists at home and abroad, that recruitment in the United States is being pushed forward vigorously but that, in any case, the "central problem" is to strengthen British industry and help it to make proper use of graduates. "It is not really the government who are alone in the dock today." But Mr. Benn also wanted the universities to change their outlook about the value of careers in business. He agreed with Mr. Hogg about the need for European projects, but was hopeful about the plans being laid by the British Government. Mr. Crosland argued that the brain drain worked in two directions, with people moving from other countries to the United Kingdom and with emigrants returning after a spell abroad. Of the fellows of the Royal Society, 10 per cent were born abroad. But the problem is "concentrated in the last analysis on the policy, attitude and demands of the United States", and it could become more serious if the demand for skilled people in North America continued to increase as quickly as it had been doing. According to Mr. Crosland, a continuing failure on the part of British industry to attract bright graduates from the universities is also a possible cause of aggravation of the problem. He was all for more vigorous attempts by industry to make better use of scientists, as well as for attempts to induce more emigrants to return to Britain. He did not share the Opposition's view on taxes, however, and argued that the people who go abroad to work are not to be found among those on whom the marginal rate of tax is very great.

## University News:

### London

PROFESSOR L. COOPER, at present professor of mathematics in the University of Toronto, has been appointed to the chair of mathematics tenable at Chelsea College of Science and Technology. The title of professor of pure mathematics has been conferred on Dr. K. W. Gruenberg, in respect of his post at Queen Mary College, and the title of professor of cell chemistry has been conferred on Professor K. S. Kirby, in respect of his post at the Institute of Cancer Research: Royal Cancer Hospital.

### Manchester

DR. J. A. DAVIS, at present reader in paediatrics in the Institute of Child Health, University of London, has been appointed professor of child health and paediatrics and director of the Department of Child Health, on the retirement of Professor W. F. Gaisford.

### Mount Allison, Canada

MOUNT ALLISON UNIVERSITY in New Brunswick, Canada, announces the establishment of a Ruggles Gates Chair in Biology. The chair was endowed by the late Professor Reginald Ruggles Gates, who obtained his B.A. and M.A. degrees at Mount Allison. The university has inaugurated a Gates Memorial Collection, to consist of his books, papers, and other items of personal property. The first Ruggles Gates professor of biology is Professor W. B. Stallworthy, who has been professor and head of the Department of Biology since 1956.

### Sheffield

DR. B. RAWLINGS, at present reader in civil engineering in the University of Sydney, has been appointed to the second chair of civil and structural engineering, and Dr. D. E. Newland, at present senior lecturer in mechanical engineering at Imperial College of Science and Technology, London, has been appointed to the second chair of mechanical engineering.

## Appointments

MR. D. H. HILL, of the United Kingdom Atomic Energy Authority, has been appointed first secretary (atomic energy) to the U.K. delegation to the European Economic Communities in Brussels.

## Announcements

At a general meeting, held at Hyderabad on January 3, the Academy of Zoology elected the following officers and members of the executive council for the triennium 1967-69: *President*, Prof. B. C. Mahendra (India); *Vice-Presidents*, Prof. E. H. Rapoport (Argentina), Dr. G. Schreiber (Brazil), Dr. F. Turček (Czechoslovakia), Dr. F. H. Glenny (U.S.A.), Prof. M. Ghilarao (U.S.S.R.); *Secretary*, Miss S. Sharma (India); *Joint Secretary*, Prof. S. Sharma; *Treasurer*, Mr. D. Charan; *Members of the Council*, Dr. R. L. Peterson (Canada), Prof. P. Heegaard (Denmark), Dr. T. A. Moussa (Egypt), Prof. J. Z. Wylezynski (France), Prof. W. Ullrich (Germany), Dr. A. Keve (Hungary), Prof. G. P. Sharma (India), Marquis N. Kuroda (Japan), Prof. J. ten Cate (Netherlands), Prof. W. E. Adams (New Zealand), Prof. G. Paspalev (Bulgaria), Prof. L. Fah-Hsuen (Taiwan), Dr. A. d'A. Bellairs (United Kingdom), Dr. A. Grobman (U.S.A.), Prof. H. M. Smith (U.S.A.).

DEAN N. J. PALLADINO of the Pennsylvania State University has been elected chairman and Dr. C. W. Zabel of the University of Houston has been elected vice-chairman of the U.S. Atomic Energy Commission's Advisory Committee on Reactor Safeguards for 1967.

THE John Murray Travelling Studentships for 1967 have been awarded by the Royal Society to Dr. A. E. Gill,

assistant director in research in dynamical oceanography, Department of Applied Mathematics and Theoretical Physics, University of Cambridge, and Mr. P. D. V. Savage, research student in the Department of Oceanography, University of Southampton.

DR. N. BEKKEDAHL, deputy chief of the Polymers Division, Institute for Materials Research, National Bureau of Standards, has been awarded the 1967 Charles Goodyear Medal by the Division of Rubber Chemistry of the American Chemical Society.

THE Ministry of Technology has produced a new booklet, *Register of Research in Machine Tools 1966-67*, which records briefly research work on machine tools and associated topics being carried out by the Ministry's research stations, and by research associations, universities and similar organizations. Copies can be obtained free from Publications Section, Ministry of Technology, Abell House, John Islip Street, London, S.W.1.

A NEW publication entitled *Journal of Molecular Structure* is to be published by Elsevier Publishing Company. Further information can be obtained from Elsevier Publishing Company, P.O. Box 211, Jan van Galenstraat 335, Amsterdam.

THE first issue of a new journal entitled *Journal of Experimental Marine Biology and Ecology* is scheduled to be published by the North-Holland Publishing Company in June 1967. The publication will be devoted to all aspects of the biology of living organisms in the marine environment.

MR. ROBERT FROMAN, P.O. Box 322, Garnerville, N.Y. 10923, is compiling a list of ways in which amateurs can make meaningful contributions to scientific work. He would welcome suggestions, which should be sent to him at his address.

THE Endeavour Essay Competition has once again been arranged by Imperial Chemical Industries Ltd. in conjunction with the British Association for the Advancement of Science. Prizes totalling over £200 are to be awarded by Imperial Chemical Industries, Ltd., and the prizewinners will also receive invitations to attend the whole of the British Association meeting at Leeds in 1967. Further information about this competition can be obtained from the Deputy Secretary, British Association for the Advancement of Science, 3 Sanctuary Buildings, Great Smith Street, London, S.W.1, and the envelope should be marked Endeavour Prize Essay.

A SHORT course on "The Safe Use of Electricity in Industry" will be held in the University of Bradford during March 9-11. Further information can be obtained from the Registrar, University of Bradford, Bradford 7.

AN Anglo-German welding conference is to be held in Düsseldorf during April 4-7. Further information can be obtained from Mr. L. W. Booth, The Institute of Welding, 54 Princes Gate, Exhibition Road, London, S.W.7.

A SYMPOSIUM on "Mechanical Design of Diesel Engines" is to be held at the Institution of Mechanical Engineers during March 1-2. Further information can be obtained from the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1.

A SHORT course on "Modern Developments in Bridge Design" will be held in the University of Bradford on Tuesday evenings between March 7-May 9. It is intended for practising engineers interested in the analysis and design of bridges. Further information can be obtained from the Registrar, University of Bradford, Bradford 7.

AN international symposium on "Modern Optics", organized by the Polytechnic Institute of Brooklyn, will be held in New York City during March 22-24. Further information can be obtained from Mr. Jerome Fox, MRI Symposium Committee, Polytechnic Institute of Brooklyn, 333 Jay Street, Brooklyn, N.Y. 11201.

A CONFERENCE on "Underwater Archaeology", sponsored by the University of Miami Division of Continuing Education and the Council of Underwater Archaeology, will be held in Miami during March 23-25. Further information can be obtained from Mr. Sanford Schnier, University of Miami News Bureau, Coral Gables, Florida.

A CONFERENCE designed to stimulate research and development of electrical power systems for automobiles, trucks and buses as a major step in reducing air pollution will be held in the University of Columbia during April 6-8. Further information can be obtained from Professor H. P. Gregor, Polytechnic Institute of Brooklyn, 333 Jay Street, Brooklyn 1, New York.

CORRIGENDUM. In the article entitled "Structure of Ribonuclease" by Dr. C. H. Carlisle *et al.* (*Nature*, 213, 557; 1967), the table of approximate cystine positions on p. 561 should be deleted and the following substituted:

I-VI	$x = 0.83, y = 0.85, z = 0.1$
II-VII	$x = 0.02, y = 0.25, z = 0.17$
III-VIII	$x = 0.28, y = 0.08, z = 0.43$
IV-V	$x = 0.90, y = 0.95, z = 0.42$

ERRATUM. In the article "Safeguards on Plutonium", by Leonard Beaton (*Nature*, 212, 1517; 1966), in line 14 of the paragraph headed "Options on Bombs" on page 1519 there appears the phrase "the private activity of the United States Atomic Energy Commission and certain politicians in the know". Mr. Beaton had written "the private activity of the A.E.C." and was not intending to refer to any particular public authority.

## THE NIGHT SKY IN MARCH

All times are in Universal Time

PLANETS	MOON				CONJUNCTIONS WITH THE MOON			
	New Moon		Full Moon					
					Venus	18d 21h, 1° N.		
					Mars	27d 22h, 2° N.		
					Jupiter	21d 07h, 5° S.		
					Saturn	—		
Times of rising (R) and setting (S) during the month								
Name	R/S	Beginning	Middle	End	Mag.	$D_9$ (10 <sup>6</sup> miles)	Zodiacal position	
Mercury	S	18h 15m	Unfavourable for observation			+1.3	62	Aquarius
Venus	S	20h 05m	20h 55m	21h 45m	-3.4	129		Pisces
Mars	R	22h 20m	21h 20m	20h 05m	-0.6	69		Virgo
Jupiter	S	5h 20m	4h 20m	3h 20m	-2.0	437		Gemini
Saturn	S	19h 20m	Unfavourable for observation			+1.2	975	Pisces

$D_9$  is the distance of planet from the Earth on the 15th of the month.

### OTHER PHENOMENA

13d 21h	Venus occulted by the Moon, visible in S. America.
21d 08h	Equinox
25d 05h	Uranus 3° S. of Moon

# Blackett on British Technology

Professor P. M. S. Blackett, President of the Royal Society and Special Adviser to the Minister of Technology, addressed the Parliamentary and Scientific Committee after lunch on February 16. What follows is an extract from his address.

My first comment is that I am an optimist about the future. Not, however, because I think most things are right—on the contrary, I think very many things are wrong—but, and here is an essential point, they are wrong in a way which can be understood and which can be put right reasonably quickly. As an experimental physicist, I know that the real moment of pessimism is when one cannot find out why one's apparatus will not work. As soon as one has found out what was wrong, then optimism returns, even if one has to scrap and rebuild a lot of the apparatus.

On higher education and pure scientific research, I will have little to say—mainly because I think our present system on the whole is good. Of course, there are defects. But many of the essential changes are in process of being carried out: and indeed have been under way for the past five years or so. The main changes needed are more university places, more universities trying out new methods, more emphasis in schools and universities on technology, more scientists taking up careers in industry (especially physicists), more emphasis on postgraduate studies (including management studies), closer contact of universities and industry.

As I have said, I am optimistic about the state of our universities and of fundamental science. I also, of course, recognize the great increase of government money which has made these results possible. I must confess, however, that I am concerned at the recent increase of fees for overseas students. Many of my scientific colleagues have eloquently criticized this action. In general, I agree with their main criticisms. In particular, I am worried at the possible damage to the postgraduate schools of our universities just at the time when it has become national policy to build them up. It is in the postgraduate schools of universities where the internationalism of learning bears most fruit.

Perhaps the most urgent task for many industries, in my view, is to rationalize their structure, preferably on their own initiative and without waiting for the Government, into fewer, larger and more specialized firms. These changes would, of course, bring longer manufacturing runs and so should achieve marked economies of scale. Most important of all, perhaps, the reduction in the number of firms and the increase of their size would allow a decisive increase in the available number of qualified scientists and engineers in each firm for all the stages of my chain, in particular for the building up of R & D groups of adequate size to be viable. It would also allow the best managers to be better utilized.

Of course, merging is only one way of getting larger firms quickly. The more usual method, and perhaps the more important, is by rapid growth of a single firm—perhaps initially quite a small one—under first-class management. I am convinced that in many cases the Government should assist such go-ahead firms in a deliberately selective way. Though I can understand how unpopular selective measures are in many parts of industry, I am convinced that only by some form of selective concentration of our technological, manufacturing and industrial resources in strong firms can Britain compete internationally in many advanced products. Selective financial assistance to selected firms from the Government

is especially needed when the main competition comes from foreign and international firms, like many in the U.S.A., which have been heavily financed by fall-out from space or defence contracts. Obvious examples are computers, instruments, microcircuits and aircraft.

I now want to discuss some aspects of government procurement. Recently it has been realized that some of the traditional methods of procurement by central government or by state corporations and authorities could be improved if the objective were accepted of bringing into being a few really first-rate and internationally competitive firms.

My second criticism is a very familiar one and relates to the practice of some Government agencies of spreading their orders for some products—for instance, heavy electrical equipment—round too many firms, so perpetuating fragmentation of R & D teams or even increasing it, as well as denying the advantages of scale in manufacture.

My third criticism relates to a fairly common failure of a Government agency, when placing a development contract with a firm for some product which the Government will itself purchase for its own needs, to so modify the specification as to make the product more saleable at home and abroad.

My fourth and last criticism of the Government today—I have plenty more ready for other occasions!—relates to some of the R & D programmes carried out in government research establishments and the use made of the results. For one thing, there is often a great lack of cost-consciousness. This has provoked some industrialists to accuse some government establishments of designing gold bricks. Then, when an establishment has completed some R & D programme it is quite usual to make the results available to all the relevant firms—in the sacred pursuit of fairness. In fact, it often happens that no British firm can profitably take it up without some degree of monopoly right in it, so no firm takes it up. The R & D is thus wasted. If and when the results are actually published, as they often are, then it is quite likely that they will be exploited first by quick-off-the-mark foreign firms.

The more general problem of the role of R & D effort in government stations and in industry raises very delicate questions. I have slowly come to the conclusion that Britain after the war inadvertently took a wrong turning when it continued to rely so much for defence and atomic energy R & D on its own government stations, rather than on industry. I believe that in the U.S.A. a bigger fraction of government funds for defence and atomic energy went to industry and less to government stations. Few would now doubt that the United States has gained greatly from the resulting strengthening of industry and the building up of very strong firms, and that Britain has lost relatively.

On the other hand, for long pay-off time projects, say 10 to 20 years, the less commercial atmosphere of some government stations may be an advantage. A major national problem today is how to divide our total technological resources between long and short pay-off investments and between government stations and industry. A high level of technological, economic and industrial statesmanship will be needed to solve this problem.

# Coding in the Auditory Nervous System

by  
I. C. WHITFIELD

Neurocommunications Research Unit,  
University of Birmingham

Experiments on how hearing works suggest that it is the connectivity of the central pathways, and not the existence of elaborate code patterns in individual structures, which mediates discrimination of such a wide range of sounds by the ear:

THE idea of auditory analysis by resonant structures is one of some antiquity. The earliest theories were framed in terms of cavity resonances, for the inner ear was then thought to be filled with air. Quite explicit theories of this type are to be found at the beginning of the seventeenth century. From the time of du Verney<sup>1</sup> onwards, however, the solid structures to which the auditory nerve is distributed came to be regarded as the resonators, and the only changes between 1700 and 1850 resulted from a continuing search for the precise location of the resonators, the field of search being progressively opened up by improvements in microscopic and histological technique. The postulated resonance seems to have been regarded mainly as a means of magnifying the weak sound stimulus rather than as an analytic mechanism, although du Verney did consider that as a result of differential vibration the auditory nerve would "receive different impressions which represent in the brain the various characteristics of tones". Haller<sup>2</sup> appears to have been the first to speculate on the possibility of distinguishing sound frequencies by the frequency of the 'tremors' in the auditory nerve fibres and thus to have foreshadowed the other great group of auditory coding theories—the frequency or "telephone" theories first formalized by Rutherford in 1886.

In 1857 Helmholtz<sup>3</sup> produced his famous theory, which can probably be regarded as the first attempt to formulate a detailed system of auditory coding. He did this by combining three previously enunciated principles. The first of these was Ohm's law of auditory analysis. It is a matter of common experience that, in notes sounded by most musical instruments, it is possible with practice to distinguish both the fundamental and one or two overtones. Ohm extended this observation in his hypothesis, and stated that any complex periodic sound wave behaved—as far as the ear was concerned—as if it consisted of a series of suitably related sine waves corresponding to its Fourier components.

Helmholtz was quick to recognize that a system of tuned resonators is precisely the kind of structure to realize Ohm's proposal physically, and he therefore emphasized the analytic rather than the magnifying properties of the resonance hypothesis of cochlear function already established.

The third principle was that which is now commonly known under the name of Müller's doctrine of specific nerve energies. Müller proposed, in effect, that there are five different kinds of sensory nerves—one for each of the five senses—and that stimulation of one particular kind of nerve, by whatever means, evokes specifically the sensory quality to which it is related. Other people carried the subdivision further and the idea reached its fullest extension with Helmholtz's proposal of a specific fibre or group of fibres for each distinguishable pitch. The Helmholtz theory, in its original form, was a pure place theory. Each subjectively distinguishable tone

had a corresponding resonator in the cochlea and each resonator was supplied by an individual nerve fibre or group of fibres distinct from all others. Frequency was thus coded in terms of activity or inactivity in particular fibres, and intensity in terms of the degree of that activity.

There are a great many problems raised by the Helmholtz hypothesis, of most of which Helmholtz was himself aware. It is not possible to discuss them in detail here; they have been well treated by Wever<sup>4</sup>. It is sufficient to point out the two general headings: the identity of the resonators, and their selectivity. In spite of the greatly increased detail which the compound microscope had revealed by the mid-nineteenth century—in particular the structure of the organ of Corti—it never proved possible to identify any component which would account in number and range of physical properties for the number and range of the known discriminable frequencies. Likewise, it proved impossible to reconcile the high degree of selectivity called for in the resonators with the experimentally determined decay time of the system.

These two difficulties caused Helmholtz later to abandon the idea of highly selective resonators and to suggest only that one particular resonator was most highly excited by a tone while those for some distance on each side would be excited to lesser extents. He thus implicitly abandoned the specific nerve energy "one tone, one fibre" code in favour of a code in which there was a non-unique array of fibres subjected to a unique pattern of activation.

Although both the general principle and the details of resonance in the cochlea continued to be matters of argument, the theory was quite widely accepted and taught in elementary textbooks for some seventy years. Perhaps its very elegance and simplicity made people feel it ought to be true and encouraged its acceptance.

## Behaviour of the Cochlear System

The essence of the Helmholtz theory was a series of transverse mechanical resonators, distributed along the length of a tapering basilar membrane. Tones of different pitch would set into vibration different but highly localized regions along the length of this membrane. Until the early 1940s no one had actually looked at the basilar membrane during activation of the ear by a sound stimulus. Then Békésy<sup>5</sup>, who had been working for some time on cochlear models, published several papers on the mechanics of real ears. The essence of his method was to examine the vibrating membrane through an artificial window in the cochlea with the aid of stroboscopic illumination. He found indeed that there was a region of maximum vibration of the membrane for a given frequency of stimulus, and that this maximum moved from the apex towards the base of the cochlea as the sound frequency was increased. The maxima were not very sharp, however, and considerable overlap of the vibration envelopes was evident between frequencies an octave or more apart. The method also made it possible to determine the

relative phase of the vibration, and the result proved crucial against a resonance theory. The phase lag of displacement of the basilar membrane relative to the driving force increases progressively from the base to the apex of the cochlea, reaching values as large as  $5\pi$  at the apical end; the lag at the position of maximum displacement may be  $2\pi$  or more. These values are not compatible with a true resonant system. The disturbance can best be thought of as a travelling wave originating at the basal end of the membrane and travelling towards the apex of the cochlea. As it travels it gradually increases in amplitude and then dies away rather abruptly. With high frequency driving forces the peak amplitude is reached close to the basal end, and the wave does not travel very far before dying out. With lower driving frequencies the wave travels farther and farther along the cochlea, and the maximum is progressively displaced towards the apical end (Fig. 1).

Fig. 1. "Instantaneous" pictures of the travelling wave on the basilar membrane for a high frequency, *a*; a middle frequency, *b*; and a low frequency stimulus, *c*. The dashed envelopes show how the disturbance travels farther along the membrane from base to apex before reaching a peak and dying out.

The basilar membrane carries on its surface a rather complex structure known collectively as the organ of Corti. This structure contains the hair bearing cells which form the mechano-neural transducers. Vibration of the basilar membrane results in deflexion of the hairs attached to these cells and this, in turn, by a process not fully understood, results in a discharge of impulses in the sensory nerve fibres associated with these cells. The greater the amplitude of vibration of the membrane, the faster are impulses discharged by the nerve.

Although the innervation of the cochlea is quite complex, in general terms we can say that the 30,000 to 40,000 fibres of the auditory nerve are evenly distributed to hair cells along the whole length of the basilar membrane. Because the vibration envelope of one tone can overlap that of other tones an octave or more away, and because the extent of the envelope varies with intensity, we might expect that a single auditory nerve fibre could be activated by many different tones, and this proves to be the case. Near its threshold a fibre responds to only a small range of frequency, but as the sound intensity is increased it responds over a greater and greater range until at high intensities it may be responding to any frequency within a band several octaves wide<sup>6</sup>. Each

fibre thus has a triangular frequency/intensity response area which roughly mirrors the shape of the vibration envelope.

Because any one fibre responds to a wide band of frequencies, it would be expected, conversely, that a large number of auditory nerve fibres will be discharging at any given stimulus frequency. Schuknecht<sup>7</sup> has shown that at the quite moderate sound pressure level of 40 dB, between 15 and 25 per cent of the whole system is activated by any one single frequency. But 25 per cent of 40,000 fibres is 10,000 fibres. It follows that if the frequency is changed by 1 per cent—an easily detectable change—something like 200 fibres will be added to one end and a similar number subtracted from the other. In other words, 98 per cent of the active fibres are activated by both tones. When we remember that the total number of fibres activated depends on intensity as well as frequency along the array, it is clear that there is no question of there being specific groups of fibres for specific discriminable frequencies. How then does the system function?

### Possible Pulse Interval Codes

An alternative to the resonance hypothesis was put forward by Rutherford<sup>8</sup> in the 1890s and has become known as the "telephone theory". Rutherford suggested that, rather than peripheral analysis taking place, the auditory nerve transmitted a frequency replica of the sound. Little was known in those days about the properties of the nerve impulse, but subsequent work has shown that it is not possible for a nerve to carry trains of impulses at frequencies greater than at most 1,000 per sec, and it usually cannot sustain rates greater than 500/sec for more than a very short time. This leaves a large proportion of the audible spectrum without representation. To deal with the frequencies above 500 c/s, it has been suggested that some form of alternation takes place<sup>4</sup>. According to this idea, a frequency of 10,000 c/s would be dealt with by twenty fibres each firing 500 pulses/sec and firing in rotation. Of course, this would only signal the frequency element of the sound, and considerably more fibres would be required to deal with the intensity parameter, but there are some 40,000 fibres available so that the hypothesis does not immediately fail on this score.

The primary question, however, is the experimental one: do the pulses in auditory nerve fibres bear any relation in time to the stimulus frequency? At low stimulus frequencies (say, 200 c/s) there is undoubtedly a very strong relationship. However, there is a good deal of "jitter" in the system which causes this relationship to become progressively less and less obvious as the stimulus frequency is increased. In the auditory nerve this relationship fails somewhere between 2,000 and 4,000 c/s, according to the time and space over which one chooses to integrate the measurements. The situation gets progressively worse as one ascends the neural pathway, owing to the variable nature of synaptic delays (the variation may be as much as 300  $\mu$ sec). This means, in effect, that for anything but the very lowest frequencies, a frequency code would have to be converted to some other form at a very early stage in the neural path. There is no evidence that any such conversion takes place. We do not, for example, find that single neurones at the higher levels of the nervous pathway respond only to narrow frequency bands; the band of frequencies to which a given fibre responds at, say, the collicular level is just as great as that of an auditory nerve fibre. We must conclude that although frequency representation is a possible mechanism for low frequencies, it is not a valid one for high frequencies.

Even at low frequencies there is a further problem to be considered. It is very easy when recording nerve impulses on an oscilloscope, or using them to prepare a pulse interval histogram, to distinguish a frequency of 990 from a frequency of 1,000. However, for the nervous system to do this, it too must have a suitable clock and there is no

evidence that a neural clock of this degree of accuracy exists.

We have considered two types of coding—individual channel activity and mean pulse frequency. Let us now consider another. The pulse trains in a nerve fibre are not, in detail, evenly spaced in time. This is especially true at higher levels in the system. It is clearly possible that a pulse interval code could exist, and such a code has a potentially high information capacity. In the past ten years or so, the possibility of such a code in the nervous system has attracted a lot of attention and a great deal of work has been done on analyses. So far, little encouragement has been forthcoming. Examination of such "patterns" in the auditory system has served only to support the conclusion that the distributions of pulse intervals are random.

In the early stages of the system, if we discount the relative deficiency of short intervals imposed by the refractory properties of the excitable elements, and any residual first order patterning of the type referred to here, there remains only an interval distribution which could adequately be accounted for by a random process. At higher neural levels the distributions are complicated by multiple delay paths, but there still appears nothing obviously specific to the stimulus. The objection raised here would also seem to apply even more cogently to the use of a pulse interval code: is there in the nervous system any mechanism for decoding such a pattern? Again we know of none.

### Coding of Stimulus Frequency and Intensity

Before going further, it may be worth while to consider what the auditory system actually has to do in hearing, say, a steady tone or a vowel sound. If we make measurements of the frequency and intensity difference limina (DLs) over the whole range of hearing, we can construct a two-dimensional diagram consisting of a number of cells or compartments which show at a glance the size of the DLs in any particular region<sup>8</sup>. If we count up the total number of these cells we find there are about 340,000. However, although many people have greater or lesser degrees of absolute pitch it would be absurd to suggest that anyone when presented with a tone at random can say "That is 6,130 c/s at 30 dB above threshold", and the auditory system is not called on to transmit data for any

such choice. Intensity difference limina are normally determined by comparing adjacent stimuli. Again, although speech has a highly complex waveform of potentially very high information content, little of this is used at any one time. Even highly degraded waveforms such as differentiated clipped speech yield 92 per cent intelligibility scores<sup>10</sup>. It seems that a very few frequencies, usually called the formant frequencies, or perhaps even the second formant alone, are sufficient to characterize the speech sounds as far as intelligibility is concerned<sup>11</sup>.

Let us see, therefore, how far we can get with a rather simple code. We have already seen that the pattern of activity in the array of auditory nerve fibres for a tonal stimulus is like that of Fig. 2 with fibres firing at various rates according to the degree of excitation of the part of the membrane from which they arise. In this array we could, for example, assess intensity in terms of the discharge rate of the most highly excited fibre, or by the total number of fibres carrying any activity. Likewise, we could assess the stimulus frequency by the position of the most active fibre (the position of the "peak") or by the relative position of the two ends of the array of active fibres. Neither of these two latter criteria is very good, however, as a small percentage of 'noise' pulses added at successive synaptic junctions could easily blur their locations.

Fig. 3. Transformation of pulse rate distribution in the fibre array effected by the cochlear nucleus, *a*, input pattern; *b*, output pattern. Thick lines represent a low stimulus intensity, thinner lines a high intensity. Other conventions as in Fig. 2 (after Whitfield<sup>12</sup>).

If we examine the behaviour of a single auditory fibre at a higher level beyond the first cell station (cochlear nucleus) we observe two differences from an auditory nerve fibre<sup>12,13</sup>. First, the discharge rate is no longer a monotonic function of stimulus intensity, so that intensity cannot be signalled purely in terms of discharge rate. Secondly, over a rather wide range of stimulus intensity there is little change in firing rate. The curve tends to increase rather rapidly near threshold as the intensity is raised, and then to flatten off, falling again somewhat at very high intensities. Allanson and Whitfield<sup>14</sup> have pointed out that this effect leads to a transformation in which the noise-sensitive auditory pattern is transformed into one in which all the fibres are substantially either "hard on" or "hard off" (Fig. 3). In other words, if we consider only whether there is activity or no-activity in a given fibre, then the frequency is signalled by the relative position of the two edges, and the intensity by the number of active fibres between those edges. Such an arrangement is not only very resistant to degradation, but presents the information in a form which should be eminently detectable by the nervous system which is well adapted to locating regions of abrupt change in activity.

An immediate difficulty arises. Suppose we have not one single tone as stimulus, but two or more simultaneously as will certainly occur very often in real life. Because of the considerable overlap of activity, the auditory nerve pattern might look something like Fig. 4*a*, and this, after transformation, might be expected to give rise to a single block of active output fibres indistinguishable from that produced by a single, much louder tone, the frequency of which is located somewhere between the two tones we are considering. If we actually try the experiment, we find that although the fibres in the 'overlap' region are activated by either of the two tones sounded alone, if we sound them simultaneously these fibres are actually

Fig. 2. Diagram to show the distribution of activity in the array of fibres originating from the basilar membrane. The height of each line represents the mean rate of nerve impulses in the corresponding fibre. The upper and middle diagrams represent two different stimulus frequencies, while the lowest diagram represents an increased stimulus intensity. In actuality there would be several hundred times as many fibres activated as are shown here.

Fig. 4. Input/output relations for a stimulus involving two frequencies. Note the inhibition ( $i$ ) in the "overlap" region. Conventions as in Fig. 2 (after Whitfield<sup>19</sup>).

inhibited and fail to respond (Fig. 4b). This type of inhibition is a common feature of sensory pathways<sup>15,16</sup>. The effect of its existence is clearly to preserve the identity of separate stimuli—in this case the blocks of active fibres corresponding to the two tones.

It is also found experimentally that the fibre array preserves an orderly anatomical arrangement at least as far up as the inferior colliculus<sup>12</sup>. This means that channels which are adjacent frequency-wise are also spatially adjacent. The activity in the total array in response to a complex sound signal will therefore appear rather like that shown diagrammatically in Fig. 5a.

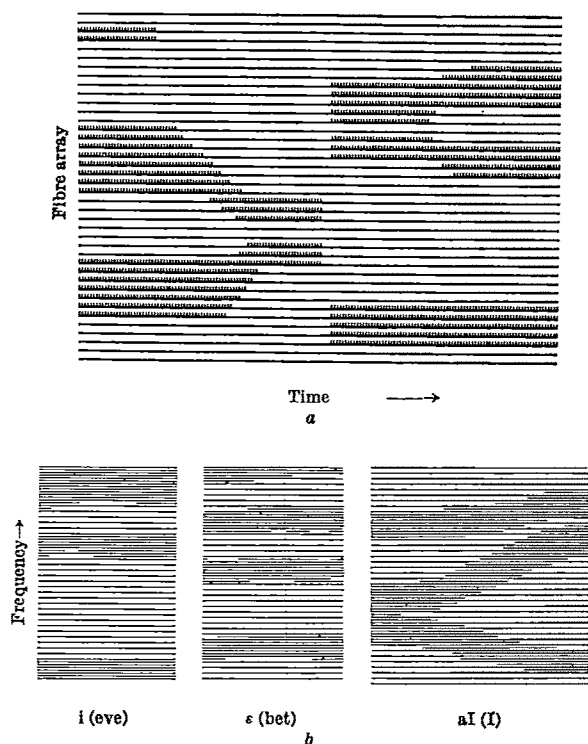

Fig. 5. *a*, Distribution of pulse activity in the array of fibres in the central auditory pathway, and the way this may vary with time as the components of the stimulus vary in frequency and intensity. *b*, Distribution of speech energy in different frequency bands for two vowels and a diphthong (after Potter, Kopp and Green<sup>20</sup>).

It is instructive to compare this with the time course of the formant frequencies of speech sounds (Fig. 5b). The evidence of Fig. 5a also suggests why discrimination between two successively presented tones, which would only require detection of the fact that the edge has moved, is so much more readily carried out than the absolute identification of frequency which would require memory identification of specific channels.

So far, we have considered only steady states and the relations between them. Identifications of frequency changes, however, are also important. For example, the feature which appears to distinguish between the consonants *b*, *d*, and *g* is whether the second formant frequency rises towards its final value, remains constant, or falls towards the final value respectively<sup>17</sup>. If we examine

neurons in the auditory part of the cerebral cortex, we find that there are such units which are specifically responsive to frequency changes<sup>18</sup>. A given neurone will fire only when presented with a falling frequency, while another will fire only when the frequency is rising (Fig. 6). The precise value of the frequency is largely unimportant provided there is a sufficient excursion in the correct direction. Provided the change is not too slow, the rate of change is not very critical.

Fig. 6. *a*, Response of a neurone in the auditory cortex to a rising frequency. The signal bar represents a steady tone of 12 kc/s which then rose linearly at the point shown to a new steady value of 13.2 kc/s. The rise time was 50 msec. In *b* the frequency returned from 13.2 kc/s to 12 kc/s in the same way; this failed to stimulate the neurone (after Whitfield and Evans<sup>18</sup>).

It seems likely that the qualities of pitch and intensity are distinguished by levels below the cortex, as discriminations of this type can be made, for example, by cats in the absence of the relevant cortical areas. Temporal patterns of sound, in which the only differences are those of the sequence of the tones and not their identity, cannot, however, be distinguished in these circumstances. There is some evidence of a similar situation in man.

#### Transient Phenomena and Sound Localization

So far we have been considering either steady state phenomena, or signals involving only fairly slow and limited changes of a single frequency. However, the ear has also to operate on a wide range of transient signals. One of the defects of the resonance theory was its failure to deal with this aspect of cochlear behaviour and its concentration on steady state frequency analysis. It is possible theoretically to produce for any waveform a pure frequency analysis, a pure time analysis, or any intermediate compromise. The mechanics of the cochlea do indeed represent such a compromise between the needs of frequency identification and the necessity for the temporal location of wave fronts. The latter are, of course, of particular importance to the organism in the location of sound sources.

If a short impulse is applied to the ear, a 'travelling bulge' is produced on the basilar membrane which propagates from the base to the apex of the cochlea. This wave has a velocity of the order of hundreds of metres per second near the base and slows to only three or four metres per second near the apex. Experiment shows that as a result of the passage of this bulge a given auditory nerve fibre discharges one or more impulses with a pulse interval corresponding to the steady-state frequency for which that fibre would be maximally excited<sup>19</sup>. There is thus a close link between the temporal pulse pattern produced by an impulse and that produced by a low frequency tone, and it would appear that the same mechanism could well process both. The 'click' has a marked superiority over the tone, however, in that it excites temporarily identifiable pulses in fibres at the basal end of the cochlea, and the steep wave front means that these initial pulses will be especially accurately timed.

For localization of a sound source, the relative time of arrival of the sound at the two ears and the relative timing of the corresponding nerve impulses could provide some of the necessary data. In criticizing the telephone and related theories of frequency analysis, we noted the way in which the relation between nerve impulse position and stimulus envelope, fairly good in the auditory nerve, became progressively degraded as more and more synapses were introduced along the pathway. We argued that this potential source of information could only be used if it

were transformed at an early stage into some other code. In the process of sound localization such a transformation does take place. There appears to be a special structure for this purpose—the medial (or accessory) olivary nucleus, which is situated in the brainstem at about the level at which the auditory nerves enter it. The nucleus is a plate like structure which has a sheet of nerve cells each innervated on one face by fibres of the auditory nerve of its own side, and on the opposite face by corresponding fibres of the auditory nerve of the opposite side. Hall<sup>20</sup>, using click stimuli, has shown that the probability that one of these cells will fire depends on the relative time of arrival of the stimulus at the two ears. Thus, if the stimulus to the ipsilateral ear precedes that to the contralateral ear by 500  $\mu$ sec the probability of the neurone firing might be, say, 0.75. If the ipsilateral stimulus lags by 500  $\mu$ sec the corresponding probability would be only 0.45. Relative intensity of the stimuli has a similar effect; if the ipsilateral click is more intense than the contralateral one, then the probability of firing is increased and vice versa. Artificial manipulation of the timing and intensity of dichotic clicks enables us to demonstrate the phenomenon of time intensity trading<sup>21</sup> in the apparent position of a source, but for a real single source the two effects reinforce one another, as the signal will be both earlier and louder at the nearer ear. Because this situation involves a higher probability of a particular cell firing, it will mean that more fibres leaving this nucleus will be activated; the code has been transformed from one in which the information is contained in the relative timing of impulses to one in terms of the number of active fibres. The end result of the transformation thus has the same form, and the same resistance to degradation, as the frequency code discussed earlier. Of course, the number of active fibres on a given side will be a function of the absolute intensity of the signal, as well as of its relative intensity, and to this extent there is an ambiguity. The relative number of active fibres, however, on the two sides is to a first approximation independent of the absolute intensity and thus could give a measure of lateralization. Although such a model has been proposed<sup>22</sup>, the anatomical site of a comparator has not yet been located. Nevertheless, at the cortex there are cells which, while they are readily activated by quite weak sounds anywhere in the quadrant from dead ahead to a position opposite one ear, are quite unaffected by much stronger signals originating in the corresponding quadrant on the opposite side of the head.

### Centrifugal Control

Finally, let me turn to the question of the control of the auditory input. Everyone is familiar with the phenomenon of "not hearing the sitting room clock tick until it stops". Continuously present or irrelevant signals tend to be suppressed at the expense of more immediately important ones. This control takes place quite early in the system. Thus the electrical response in the cochlear nucleus to a sound signal has been shown to disappear if the signal is repeatedly presented over a long period<sup>23</sup>. Distraction of attention by the presentation of an "interesting" visual stimulus may have a similar effect<sup>24</sup>.

These 'gating' operations, which selectively control the input, appear to be mediated by centrifugal pathways which parallel the ascending auditory system all the way from the cortex to the periphery. Even right out at the cochlea it is possible to inhibit activity in individual groups of auditory nerve fibres by stimulation of the centrifugal olivo-cochlear bundle<sup>25</sup>. Farther up the system, within the brainstem, the possibilities become more varied. Stimulation of one set of descending fibres will shut off the response to sound of a particular neurone in the cochlear nucleus<sup>26</sup>; on the other hand, stimulation of a different set of these fibres increases the sensitivity of cochlear nucleus cells, and may lower the sound threshold of a particular cell by as much as 15 dB<sup>27</sup>. It is clear that

these fibres control the sensory throughput at all stages. It is less clear if they simply control whether or not information gets through at all, or if they actually determine the route it takes.

Until quite recently, views on auditory localization tended towards the view that somewhere in the system there should be an area or set of structures uniquely activated by a discriminable stimulus. From this locus activity would presumably 'fan out' to produce a complex widespread response on the motor side. A diagrammatic representation might be made from two pyramids with a common apex. As we have seen, experiment simply does not support this concept of sensory organization. Just why such an arrangement should have been thought necessary is unclear. Among spinal reflexes, the classical 'scratch reflex' involves interconnection of a complex sensory pattern with a complex motor pattern, yet no one has ever postulated a 'scratch' unit or claimed that there were unique pathways leading to it. The 'pyramid' theory, if it were true, would of course have simplified our concept of the discrimination mechanism, as we should only require a gate to operate at a single point. However, the existence of widespread centrifugal connexions means that not only is diffuse gating a practical means of controlling a 'learned' discrimination, but that this gating could take place at almost any neural level. It is well established, for instance, that direct connexions exist between auditory nuclei and motor pathways at the upper medullary level<sup>28</sup>. These are generally described as 'auditory reflex' pathways, but there seems no reason why they should not be 'conditional' pathways whose activity or quiescence is controlled by the centrifugal system.

In summary, then, let me reiterate two points. There is no evidence anywhere in the auditory system for groups of neurones responding uniquely to particular discriminable stimuli, and multi-channel correspondences probably exist between the sensory system and effector systems, equivalent to those at the spinal level. The elaborateness of the sensory pathway seems to lie in its connectivity; there is no evidence to date for the existence of elaborate code patterns in individual fibres.

# Rhinoviruses: a Numbering System

Several laboratories have collaborated on a project to identify distinct serotypes of rhinoviruses, and to organize them into a convenient numbering system. They have prepared the following statement\*.

RHINOVIRUSES have emerged as the most important of the known aetiological agents of adult upper respiratory illnesses<sup>1-7</sup>. Taxonomically, they are classified as a sub-group of the picornaviruses because of certain biophysical and biochemical properties which include (1) small size (15-30 m $\mu$ ); (2) ribonucleic acid (RNA) core; (3) ether resistance; and (4) complete or almost complete inactivation at pH 3.0 (ref. 8). This last property distinguishes the rhinovirus from the enterovirus sub-group of picornaviruses.

Almost ninety rhinovirus serotypes have been described as potential new candidate viruses<sup>8</sup>. This large number of described rhinoviruses and the knowledge that many of them had not been tested by neutralization tests against all previously reported serotypes prompted the National Institute of Allergy and Infectious Diseases (NIAID) Vaccine Development Branch (VDB) and the World Health Organization (WHO) to institute a collaborative rhinovirus programme to compare the antigenic relationships of rhinoviruses in order to arrive at an acceptable rhinovirus numbering system. It was considered essential to assemble the numerous rhinovirus serotypes into a suitable numbering scheme, because the rapidly increasing number of serotypes made interpretation of epidemiological data from various laboratories difficult and also prevented many laboratories from making epidemiologic investigations of rhinovirus infection. The Vaccine Development Branch, therefore, awarded a contract to the Children's Hospital Research Foundation, Children's Hospital, Columbus, Ohio, to act as a reference laboratory with the immediate task of performing reciprocal neutralization tests with the candidate rhinoviruses and sera submitted to the programme.

At a rhinovirus workshop held on January 25, 1965, and attended by active investigators in the field, each laboratory which was represented submitted a list of candidate rhinoviruses which had been tested against all available rhinovirus antisera and which appeared to be distinct serotypes. After this meeting a few additional rhinoviruses were added to the list by various laboratories; a total of sixty-eight viruses were included in this initial phase of the programme. Participants at this workshop agreed that the following requirements were to be fulfilled before a virus was submitted to the programme as a candidate prototype. These were (1) each candidate rhinovirus was to be "purified" either by three terminal dilution passages in tube cultures or by three single plaque passages; (2) data concerning the biophysical and biochemical properties of each candidate rhinovirus were to include evidence that the virus was ether resistant, acid labile, less than 50 m $\mu$  in diameter and possessed an RNA core; (3) antigenic distinctness of the candidate rhinovirus was to be established by neutralization tests with all other known candidate antisera which were available at the time the virus was submitted; (4) evidence of human origin was to be demonstrated by a fourfold or greater rise in neutralizing antibody in paired sera from at least one person from whom the virus was obtained or recovery of the virus from two or more individuals.

Each laboratory was asked to submit to the Reference Laboratory 25 ml. (in 1 ml. portions) of each candidate virus and 100 ml. (in 2 ml. portions) of specific hyper-immune antiserum. In the Reference Laboratory each of the sixty-eight viruses was tested by the neutralization technique (using approximately 32-320 T.C.D.<sub>50</sub>) against each of the sixty-eight antisera (at dilutions of from 1:2 to 1:20) while each submitting laboratory tested its candidate virus or viruses against all available sera in a similar manner. In this way each candidate virus was tested independently against each specific antiserum in at least two laboratories. When a virus was neutralized by the screening dilution of serum, a reciprocal neutralization endpoint test was performed to determine the extent of that relationship. All the viruses included in the programme were "purified" by tube terminal dilution or plaque methods by the laboratory describing the virus except for the "coryzaviruses" 11, 12, 13, 14, 15, 16, 17, 18, 28 which were "purified" by the Laboratory of Infectious Diseases (LID), NIAID, NIH, Bethesda, Maryland, and "coryzaviruses" 19, 21, 22, 24, 25, 26, 27, 29, 30 which were "purified" by the Common Cold Research Unit (C.C.R.U.), Salisbury, England, so that these "coryzaviruses" could be included in the programme. All sera were prepared by the laboratory describing the virus, or by Abbott Laboratories, Inc., under contract to the VDB, except for sera to "coryzaviruses" 11, 12, 13, 14, 15, 16, 17, 18, 28 which were prepared by the LID, NIAID, NIH, and sera for "coryzaviruses" (CV) 24 which was prepared by the C.C.R.U. and sera for "coryzaviruses" 19, 21, 22, 25, 26, 27, 29, 30 which were prepared by the California State Department of Public Health Laboratory (Dr. Lennette). All sera used in the programme were prepared from "purified" virus except for the aforementioned sera to "coryzaviruses" 19, 21, 22, 25, 26, 27, 29, 30 which were prepared as working reagents before the collaborative programme had begun and which were only available in small quantities but were used so that these "coryzaviruses" could be included in the programme. In addition, all neutralization tests for each virus were performed by the laboratory describing the virus with the exception of the "coryzaviruses" for which most of the laboratory tests were performed by the University of Chicago (Dr. Hamre), and Echo-28 for which most laboratories performed the required reciprocal neutralization tests because reagents for this virus were available to most laboratories before this collaborative programme was initiated.

In June 1966, when all the neutralization tests had been completed, a meeting on rhinovirus nomenclature was held, which was attended by all the collaborating laboratories with the exception of the Common Cold Research Unit of Salisbury, England. Data from the Salisbury laboratory were presented to the meeting.

At this meeting each laboratory presented the cross-neutralization data on the viruses which they had submitted and these results were compared with those of the Reference Laboratory. There was complete agreement among the collaborators and the Reference Laboratory with regard to major cross-reactions. Various collaborating laboratories reported minor cross-reactions. In the Reference Laboratory, however, it was observed that treatment of the sera with human liver powder eliminated these minor cross-reactions in almost all instances. A

Jordan, jun., E. H. Lennette, J. L. Melnick, W. J. Mogabgab, M. A. Mufson, C. A. Phillips, J. H. Schieble and D. A. J. Tyrrell.

complete description of the results of the neutralization tests carried out by the Reference Laboratory will be presented in a later communication from that laboratory<sup>10</sup>.

A candidate rhinovirus was considered to be distinct if at least twenty times the limiting concentration of specific antisera which neutralized 32–320 *T.C.D.*<sub>50</sub> of the other serotypes (that is, 20 antibody units) failed to neutralize 3–320 *T.C.D.*<sub>50</sub> of the candidate virus and if at least 20 antibody units of serum to the candidate virus failed to neutralize 32–320 *T.C.D.*<sub>50</sub> of each of the other serotypes. Of the sixty-eight viruses submitted to the programme six pairs of viruses and three groups of three viruses were found to be identical by the aforementioned criteria; this reduced the number of candidate rhinoviruses by twelve. In addition the only viruses which were found to be significantly related, but not identical, were Echo-28 and B632. After reviewing all available data, it was agreed that B632 be designated a sub-type of Echo-28. It was the unanimous agreement of the participants that the prototype strain among identical viruses should be that virus which was first described in a scientific publication or, if not yet described, then that

virus which was first submitted to the Reference Laboratory.

It was also unanimously agreed that a rhinovirus numbering system should be based on a strict chronological system, that is, precedence in number should be given to the virus which had been described earlier in the literature, or, if not yet described, precedence in number should be given according to the date the virus was submitted to the Reference Laboratory. According to these agreements a system of numbering rhinoviruses from 1 to 55 with one sub-type was unanimously adopted.

After this meeting, the data and numbering system were presented to the collaborators at the Common Cold Research Unit, Salisbury, England; they endorsed the system. The nomenclature system was also presented at the meeting of the Directors of the World Health Organization Respiratory and Enterovirus Reference Centres in Moscow, U.S.S.R., who unanimously approved it and suggested its publication as soon as possible. They also recommended that the numbering system be presented to the International Sub-committee on Virus Nomenclature for their information. The numbering system approved by the collaborating laboratories is shown in Table 1.

A second phase of the programme is now in progress, and additional viruses will be tested against the fifty-five numbered rhinoviruses, to determine whether they represent new serotypes. Some viruses were received at the Reference Laboratory too late to be included in the first phase and others were excluded for other reasons. For example, one large group of viruses, the "coryzaviruses" 20 and 34–53, could not be included because neither terminally diluted virus nor adequate amounts of antiserum were available. CH 82 (CHV/3/59) virus which was submitted to the first phase could not be included because untreated antiserum against this virus showed high level non-specific neutralization to many rhinoviruses<sup>1</sup>. The D.C. virus, first described in 1953, was not submitted to the first phase of the programme<sup>2a</sup>. These and other candidate rhinoviruses will be investigated in the second phase of the collaborative programme.

Investigators who wish to submit rhinoviruses for investigation in the programme should contact either the Laboratory of Infectious Diseases, NIAID, NIH, Bethesda, Maryland (Dr. A. Z. Kapikian), or the Common Cold Research Unit, Salisbury, England (Dr. D. A. J. Tyrrell)—both laboratories are designated as WHO International Reference Centres for Respiratory Diseases Other Than Influenza.

\* Virus in parentheses represents a virus submitted to programme by a collaborating laboratory and found to be identical to the prototype strain; virus in brackets represents a virus not included in first phase or not submitted to programme and found to be identical with the prototype strain by a collaborating laboratory. Reference numbers are shown in a similar manner to above. Thus, reference number not in parentheses refers to prototype strain, number in parentheses refers to virus strain in parentheses. Number in brackets refers to virus strain in brackets.

† CH 79 was formerly designated as CHV/2/59; CH 202 formerly designated as CHV/7/59; CH 310 formerly designated CHV/1/60. The number immediately following any CV ("coryzavirus") designation in this table represents a type number assigned to the indicated strain by the investigators originally describing that strain (18, 26). "Coryzavirus" was the term originally used to describe these strains (15, 18, 26).

## BOOK REVIEWS

## THE BIRTH OF AVIATION

## The Invention of the Aeroplane (1799-1909)

By Charles H. Gibbs-Smith. Pp. xxiii + 360. (London: Faber and Faber, Ltd., 1966.) 84s. net.

CHARLES GIBBS-SMITH's latest book recalls so vividly the birth of aviation that one is left with a strange sense of disbelief that the modern world of supersonic and space craft is barely half a century away from the epoch making events which he portrays. The story of man's struggle to fly is told in this book with a good balance between detail and narrative and with the support of over 250 contemporary photographs and many diagrams. The book surveys methodically the evolution of the aeroplane from Sir George Cayley's first design in 1799 to the successful meeting at Rheims in 1909 when man's conquest of the air was proved beyond all doubt and the world was left wondering, with good cause, whether this new invention would be for good or evil.

The years from 1799 to 1899 take up only the first seven short chapters under the heading of "The Fore-runners", of whom perhaps Sir George Cayley is the best known. Although brief, this section makes most interesting reading and the many excellent photographs are of considerable historical interest. The author is, however, primarily concerned with the critical decade between 1899 and 1909 to which some 200 pages are devoted. The progress in this period is dealt with in great detail in some sixty short chapters profusely illustrated and clearly written, with shrewd comment on men and machines which in total makes an interesting story as well as a historical survey.

The courage and determination of the men who made (one hesitates to say "designed") and flew these strange aircraft are now part of history, and are clearly shown in the many chapters which cover this important decade. So, too, are their squabbles without which, unfortunately, no history would be complete, but it is hard to believe that the Europeans, in their rivalry with the Wright brothers, were as stupid as the author suggests and continues to suggest to the point when the repetition becomes irritating and tends to spoil an otherwise excellent narrative.

The rest of the volume is concerned with special chapters and appendixes (of which there are eight). Balloons and airships are dismissed briefly in one chapter and engines and propellers in two, while Bleriot's historic Channel crossing in 1909 is also dealt with in one short chapter. The illustrations in all these chapters are, however, up to the high standard maintained throughout

the book. The important meeting at Rheims in August 1909 is covered in one chapter and one appendix which latter, incidentally, consists of contemporary reports from *Flight* and extends for some twenty pages of most interesting reading. Chapter 67 describes in some detail the six key aeroplanes flying at the Rheims meeting: Wright, Voisin, Henry Farman, Curtiss, Bleriot and Antoinette. Specifications are given together with full page plates of the general arrangement drawings which, although rather crude, give considerable general information of the type when examined in conjunction with the text. It is, however, unfortunate from the engineer's point of view that it has been found necessary to omit from the text the detailed illustrations which are necessary for a better technical understanding. The control systems of these same aircraft are illustrated and described in Appendix VI.

The remaining appendixes include a chronological list of the first powered aeroplanes in order of their first take-offs and a very detailed table of the first powered flights and take-offs, while another appendix lists the first aero-engines.

Throughout the book there is a wealth of data mostly of a general or semi-technical nature—including the main dimensions of the aircraft, the power of the engine, comparative performances—but there is a lack of detailed aerodynamic and structural data. Because of this, the book cannot be classed as a technical work, as the title might imply to anyone unfamiliar with the works of Mr. Gibbs-Smith. This will, however, in no way detract from the value of the book to the type of reader for whom it is intended, and while an aeronautical engineer may not find the detailed information which he may seek either in the text or through the bibliography he will find much to interest him.

The book is beautifully produced throughout, but particular mention should be made of the excellent standard of reproduction of the many illustrations. On a critical note, however, the short chapters or sections tend to give a disjointedness in reading and have resulted in some duplication of subject matter, a fault which is exacerbated by the use of a final section of notes relating to various chapters.

These are small criticisms, however, which detract only slightly from an excellent publication, obviously compiled with meticulous care and which, for such a production, is offered at a very reasonable price. A well written history of any science or technology is of interest and value to both student and expert, and this is particularly true of Charles Gibbs-Smith's latest book. It is a worthy addition to the bookshelf of anyone interested in aeronautics.

J. T. HENSHAW

## CHLOROPHYLL COMPENDIUM

## The Chlorophylls

Edited by Leo P. Vernon and Gilbert R. Seely. Pp. xv + 679. (New York: Academic Press, Inc.; London: Academic Press Inc. (London), Ltd., 1966.) \$25.

THE older literature on chlorophyll has been comprehensively and critically reviewed in a number of books, such as the third volume of Fischer and Orth, and *Photosynthesis* by E. Rabinowitch; but the progress in this field has been so rapid, especially in the past ten years, that an increasing need has been felt for some time for a new consideration of the facts.

A recent conference organized by NATO has summarized the present situation and its deliberations are being published in two volumes. Apart, however, from progress reports, which necessarily deal primarily with individual contributions, there is a need for authoritative reviews covering objectively all the most important aspects of chlorophyll research. This has been done successfully in

(continued from previous page)

<sup>26</sup> Hamparian, V. V., Leagus, M. B., and Hilleman, M. R., *Proc. Soc. Exp. Biol. and Med.*, 116, 976 (1964).

<sup>27</sup> Submitted by Dr. E. H. Lennette and Dr. J. H. Schieble, California State Department of Public Health, Berkeley, California.

<sup>28</sup> Melnick, J. L. (personal communication).

<sup>29</sup> Andrewes, C. H., Chaproniere, D. M., Gompels, A. E. H., Pereira, H. G., and Roden, A. T., *Lancet*, i, 546 (1953).

*The Chlorophylls* under the editorship of Dr. L. P. Vernon and Dr. G. R. Seely. It is somewhat invidious to single out individual chapters. H. H. Strain and W. A. Svec have reviewed the methods used in preparation, estimation and isolation of the chlorophylls, a field to which they themselves have made important contributions. Apart, perhaps, from avoidable repetition they give a critical and helpful account of the methods available, and in particular emphasize the difficulties, which have not all been completely resolved.

Holt gives a valuable account of recently discovered chlorophylls, and he deals in particular with the chemistry of chlorobium chlorophylls 650 and 660. This chapter, however, might have been improved by quoting findings and interpretations which are at variance with Dr. Holt's own work. The biosynthesis of these compounds raises a number of interesting questions which have not yet been adequately answered. The chemical synthesis of chlorophyll *a* is discussed by Dr. Lwowski; the contrast between the approach of Fischer and that of Woodward is an interesting demonstration of on the one hand supreme competence based on the classical organic chemistry of the German school, and on the other of the magnificent achievement which rests largely on the use of modern concepts to predict the reactivity of certain groups in complex molecules. Katz, Dougherty and Boucher give a valuable account of the use of infra-red and nuclear magnetic resonance spectroscopy in chlorophyll chemistry.

The state of chlorophyll in plants or micro-organisms is not yet completely understood. The nature of the linkage between chlorophyll and its associated protein is still somewhat uncertain and so are the chemical or structural factors which endow certain chlorophyll molecules with special reactivity. Our knowledge in this field and the uncertainties are clearly indicated in the chapters dealing with the optical properties of chlorophylls and chloroplast structure, and the description of the photosynthetic apparatus in micro-organisms.

Protochlorophyll is ably discussed by N. K. Boardman and the biosynthesis of the chlorophylls is reviewed by L. Borograd, both of whom give a fairly complete and up to date account of their respective topics. In some ways, however, the most interesting chapters are those written by Seely and by Vernon and Bacon Ke. There is a certain amount of overlap between these two chapters and there is also unavoidably a certain bias in the treatment of what are still regarded as controversial subjects. The reader cannot but be impressed, however, with the sophistication of the techniques used and the difficulties inherent in obtaining information about events which of necessity proceed extremely rapidly. Both these chapters give a useful, informative and helpful account of results obtained, and also of problems presented by the interpretation of the results. Altogether, the book will be most valuable to the many scientists interested in botany, microbiology, biochemistry and also to those engaged in research on chlorophyll.

A. NEUBERGER

## MORE ABOUT SPORES

### Spores

*Their Dormancy and Germination.* By Alfred S. Sussman and Harlyn O. Halvorson. Pp. xi + 354. (New York and London: Harper and Row, Publishers, Inc., 1966.) \$14; 112s.

In this book two American workers, one a bacteriologist who has been concerned with the physiology of bacterial spores, and the other a mycologist who has concentrated on the behaviour of *Neurospora* ascospores, attempt to "highlight the common denominators in biological dormancy". They extend their treatment to germination.

A brief account of the structure of dormant spores is followed by a consideration of their powers of survival.

The American interest in space leads to a review of the possibility of spores remaining viable there, and the panspermia idea of Arrhenius is given a new airing. The structural changes involved in germination and its kinetics are discussed. Two chapters deal with the environmental influences on germination and the ways in which the process may be "triggered". There is a useful discussion of the physiological and biochemical changes during germination. The controlled synchronous development of biochemical activity in a population of germinating spores offers a beautiful system for the analysis of awakening metabolism. This is a matter of present day interest in a number of laboratories in various parts of the world.

In attempting to bring together information on bacterial and fungal spores, the authors are doing a service to microbiology. It is, however, clear that they have found it difficult to compose an opera with two stars, bacterium and fungus. Rarely do these appear on the stage together; there are few duets.

The book is well produced and is a credit to the publishers, but there are numerous misprints and slips—for example, I noted nine wrongly spelt generic names. Again in relation to mucoraceous moulds reference is made at times to zygosporangia where sporangiospores are meant, and in *Phycomyces* there is a mention of conidiospores, which do not exist in that genus. In spite of these minor blemishes, however, the book is a useful and valuable one.

C. T. INGOLD

## SYMPOSIUM ON DRUGS

### CNS Drugs

(A Symposium held at the Regional Research Laboratory, Hyderabad, India, January 24–30, 1966.) Pp. xv + 367. (New Delhi: Council of Scientific and Industrial Research, 1966.) Rs. 33.00; 66s.; \$10.

THIS publication is a compilation of the thirty-two papers presented at the meetings held in Hyderabad. Approximately half the contributions are from Indian scientists, and the others are from European or North American scientists. As the editorial committee points out in the preface, research in the field of CNS drugs has grown impressively in recent years, and has been from the outset obviously multidisciplinary. This makes it very difficult to achieve a nice balance between the various aspects of research in a meeting such as this; unhappily, the present publication fails to achieve this balance. Almost half the contributions describe structure-activity relations in various classes of centrally active drugs, both old and new (including Rauwolfia alkaloids; diazacycloalkanes; 1,4-benzodiazepines; azetidines; 6,7-benzomorphans; 6-aminoquinazolinones; 2-alkyl-3-aryl-4(3H)quinazolinones; 4 substituted 2,3-polymethylenequinolines; *N*-aryl-aryl anthranilates; tropanes; *N*- $\beta$ -phenylpropionamides and substituted diaminopyridines). These articles undoubtedly provide much valuable information to those interested in these groups of drugs. The emphasis on structure activity relations, however, inevitably means that the remaining papers are stretched too thinly over a very wide field. Half a dozen articles describe the neuropharmacology of new compounds or of substances extracted from natural products (the latter not to be scorned in a country from whose herbal medicines one of the first important tranquilizers, reserpine, was "rediscovered" only fifteen years ago). The topics of addiction, neuroendocrine relationships, sites of drug action in the CNS, and drug access to the CNS are covered well, but of necessity too briefly to be of lasting value. A lamentably small number of articles is devoted to biochemical aspects of drug action.

The symposium was published with reasonable expedition, although the quality of some of the illustrations is

poor and the publication could have been improved greatly by arrangement of the articles into sections under headings. In summary, a useful review of the chemistry and structure-activity relations of several groups of CNS drugs, but not a cohesive or representative account of research in this area.

L. L. IVERSEN

## BOOK OF BREWING

### Principles of Industrial Microbiology

By Alan Rhodes and Derek L. Fletcher. (The Commonwealth and International Library of Science, Technology, Engineering and Liberal Studies; Microbiology Division.) Pp. xviii+320. (London and New York: Pergamon Press, Ltd., 1966.) 35s. net.

THIS book is an account of the knowledge of everyday importance to the microbiologist working in the field of industrial fermentation, which is being rapidly transformed from a mysterious art to a science-based industry—beer will soon be produced according to a mathematical equation instead of the reaction of the chief brewer to a glance and a sniff at the liquor in the vat. Rather than treat each fermentation as a separate entity, which has been the usual approach to the subject, the authors have attempted to distinguish and discuss the common underlying principles. Such a unified approach to fermentation technology is clearly necessary.

This study appropriately covers the physical or engineering, biological and chemical principles. The account of the design of a fermentation unit includes the culture vessels for fermentations and equipment for recovery of products. The design of culture vessels, considering its basic importance to the whole of the technology, is dealt with superficially, but this could be a true reflexion of the industry's approach at the moment to this important subject. We learn that fermenters are designed by rule of thumb for the most part. Sterilization is also dealt with in a most elementary manner, for example, the theory of sterilization by filtration is not discussed or referred to. In the chapter on aeration and agitation, the discussion of agitation is full and stimulating. In contrast, aeration, despite the mass of information about it, is cursorily dismissed.

The technical importance of genetics and screening of organisms for useful products are effectively reviewed. The chapter on nutrition is an interesting account of media, but largely avoids the principles. The chapters on the biochemistry of fermentations provide a valuable advanced account of the latest concepts in a wide range of biosyntheses of industrial importance and their relation to basic metabolic pathways. Antibiotics, steroids, vitamins, vaccine production, food fermentation and effluent disposal are all mentioned. Important details of modern fermentation processes for the production of streptomycin, griseofulvin and tetracyclines can be found here. The main criticism of the book is that the more physical and kinetic aspects of fermentation have not been dealt with as fully as the biochemistry, although the former are of crucial importance.

The style of the writing is pleasingly concise. One is irritated by the printing of Fig. 9.3, which cannot be read without a magnifying glass, and in chapter 7 by use of the same symbol *W* for both work and width. The book is suitable for degree and postgraduate courses as well as industrial microbiologists, but the standard is uneven; for example, it is gratuitous to give the formula for converting °C to °F and even metres to centimetres.

On the whole, the authors have succeeded in their task of formulating the scientific basis of fermentation. It is a timely contribution to microbiological studies which are now the basis of a large part of the chemical and food industries.

S. J. PIRT

## CALCULATING REACTIONS

### Chemical Relaxation

An Introduction to Theory and Application of Stepwise Perturbation. By George H. Czerlinski. Pp. xiii+314. (London: Edward Arnold (Publishers), Ltd.; New York: Marcel Dekker, Inc., 1966.) 120s. net.

MEASUREMENT of the rate constants of fast reactions in solution has for a long time exercised the minds of chemical kineticists. Further zest has been added to this from a biochemical and biophysical point of view. Earlier techniques based on stationary state methods are limited to relatively few special cases. In recent years relaxation techniques have increased in importance, the best known being flash photolysis and more recently electron pulse radiolysis. In the wide field of thermal reactions the methods developed by Eigen and de Maeyer have made it possible to investigate a large number of reactions.

We have been promised a monograph by Professor Eigen himself, but as yet there only exists his excellent but rather short article with de Maeyer in *Techniques of Organic Chemistry* (Volume 8, (2) ; 1963). We are therefore indebted to Dr. Czerlinski, one of Eigen's early collaborators, for producing an introductory treatment of this important subject. The monograph deals rather broadly with the elementary theoretical background, and with the techniques of different types of equilibrium displacements, such as temperature jump, field jump, pressure jump, concentration jump as well as rapid flow with temperature jump. The treatment is somewhat uneven with regard to detail and the book is something between a monograph and a text-book; there are a number of problems at the end of each chapter which are suitable for postgraduate students.

The publication of this book will be welcome by all who are interested in this field. It will certainly be very useful until a comprehensive monograph comes from Professor Eigen himself. It is well produced with a number of good illustrations. The price seems rather high for a slim volume of this type.

J. J. WEISS

## FINDING INFORMATION

### Textbook on Mechanized Information Retrieval

By Allen Kent. Second edition. (Library Science and Documentation: a Series of Texts and Monographs, Vol. 3.) Pp. xx+371. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1966.) 85s.

Annual Review of Information Science and Technology Vol. 1. Edited by Carlos A. Cuadra. (American Documentation Institute.) Pp. ix+389. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1966.) 100s.

WHILE the use of computers for routine library operations can now be considered an accepted fact, it is still a matter for doubt as to how far mechanization will be able to go in the more specialized field of information retrieval. As Professor Kent says in the second edition of his book, "the field is still in a state of flux". It is difficult to write a good text-book in these conditions, and many changes have been made as a result of the experience gained in using the first edition. The volume still remains an excellent introduction to the subject, both for the student and for those faced with the practical problem of developing a mechanized system.

The *Annual Review of Information Science and Technology* takes over from the previous book by attempting to cover, under thirteen separate headings, the research work now being undertaken in the field of information science. It is symptomatic of this activity that more than 95 per cent of the references are to work undertaken in

the United States, and that most of this work is directed towards extending the role of computers. This annual review is the first of the series to appear, and the chapter authors have interpreted their instructions in different ways. In his chapter on evaluation of indexing systems, Bourne has attempted to cover all the work in this field since 1952, and the result is a paper of little merit. In an excellent chapter on man-machine communications, Davis only refers to papers written before 1965 to illustrate particular topics, while Menzel, in writing about information needs and users, makes no reference to earlier papers.

With further excellent chapters by Baxendale on content analysis; by Climençon on file organization; by Simmons on automated language processing; by Black and Foley on library automation; and by Sherrod on national information issues and trends, this volume should be of real value to most serious workers in the field.

## PLEASURES OF THE NEW FOREST

### The New Forest

A Symposium. Contributed by Juanita Casey and nine other authors. Pp. x+201+24 plates. (London: Phoenix House, 1966.) Revised edition. 42s. net.

THIS admirable book is, in effect, a collection of eleven essays covering some of the most endearing aspects of what is, for far too many of us, a pleasant interlude on the journey from London to the South. But for those who are prepared to linger, look and read, the New Forest has great treasures to offer, many of which are revealed here in a way that will appeal both to the student and the casual visitor. Needless to say, the plants and animals receive their rightful treatment (it is particularly good to find a whole chapter devoted to the forest pony). But we are also given glimpses of the historical background and the position of the commoners within it, the gypsies, perambulations and Beaulieu Abbey. Considering its price, the standard of production is disappointing. Several of the photographs are poor (for example, those facing page twenty-three) and indifferently reproduced. There is no index—an infuriating omission for those wishing to study the Forest seriously.

W. H. DOWDESWELL

## OBITUARIES

### Professor R. C. Punnett

REGINALD CRUNDALL PUNNETT, late Arthur Balfour professor of genetics in the University of Cambridge, died on January 3 at the age of 92. He was born in Tonbridge and graduated from Gonville and Caius College (M.A., 1902). From 1899 until 1902 he was a lecturer at the University of St. Andrews, and between 1902 and 1910 he was university demonstrator in comparative anatomy and animal morphology at Cambridge. In 1910 he became professor of biology and from 1912 until his retirement in 1940 he was professor of genetics.

With Punnett died the last of a brilliant group of investigators who at the beginning of this century took an active part in the rebirth of Mendelian genetics, and, with great enthusiasm and penetration, helped the infant science to take its first important strides. By work on invertebrates, especially nemerteans, Punnett had earlier shown himself to be a distinguished comparative morphologist, and at that time he had become interested in problems of sex determination and the sex ratio.

At the beginning of 1904 Punnett joined William Bateson in an association that became a most successful partnership. Investigations of discontinuous variation had already guided Bateson's mind in the direction fore-

shadowed by Mendel's work, and on the rediscovery of this work Bateson set out to gather a team of co-workers of which Punnett became the mainstay. Sturtevant's later remark about the *Drosophila* group at Columbia University that "it was often not only impossible to say, but was felt to be unimportant, who first had an idea" also applied to Bateson's group. It was an ideal solidarity. Intensive work with a variety of plants and animals soon gave much insight into the nature of the hereditary transmission of traits, and served to explain the causes of aberrant segregation ratios. This work also provided Punnett with effective ammunition against arguments raised by the biometrical school. The origin of new and unexpected phenotypes, in first and second hybrid generations, was explained by the interaction of independent factors (genes). A momentous experimental discovery was the finding of partial "coupling", that is linkage, which soon became a crucial tool for the establishment of the chromosomal theory of the gene. By investigating quantitative traits Punnett recognized the important role of multiple genes. Of great practical interest was his "invention" of auto-sexing—the synthetic production of breeds in which the sex of newly hatched chicks could be told from their plumage.

Punnett ranged widely in the choice of problems and of the material he used. He combined, happily, the curiosity of the naturalist and the precision of the morphologist. The clarity of his analytical mind and his great fund of information and critical judgment made him an excellent expositor of his science. His *Mendelism* of 1905 ran through seven editions and was translated into seven foreign languages; his *Heredity in Poultry* of 1923, though addressed to a more restricted audience, was equally lucid. The *Journal of Genetics*, founded by Bateson and Punnett in 1910, which was skilfully edited by Punnett until 1948, was of immense value to all geneticists. In 1912 Punnett was elected a fellow of the Royal Society; he received the Darwin Medal in 1922, and in 1948 he was made an honorary member of the Genetical Society. He was a brilliant, a good and a kind man who faced the exigencies of life with courage and equanimity.

WALTER LANDAUER

### Professor Joseph le Fleming Coy Burrow

PROFESSOR LE FLEMING BURROW, who died on January 20, aged 78, was born at Bowness, Westmoreland, in 1888. He graduated in medicine in 1910 from the University of Edinburgh, where he was president of the Royal Medical Society, a much coveted student honour. After holding several house appointments at the Royal Infirmary, Edinburgh, he moved to Leeds to become medical registrar and tutor to the professor of medicine, Dr. Wardrop Griffith. During the First World War he served in the R.A.M.C. as physician to the Second Northern General Hospital at Beckett's Park, and during the Second World War as consultant physician to the E.M.S. Hospital at Seacroft. He was appointed assistant physician to the General Infirmary at Leeds in 1919, full physician in 1929, and became professor of clinical medicine in the University of Leeds in 1937, an appointment he held until his retirement in 1948. He continued to practise as regional adviser to the then Ministry of Pensions and as consultant to the Leeds Regional Hospital Board until shortly before his death. At the age of 67 he had the courage to leave the United Kingdom for four years, and acted as medical superintendent and director of the Princess Tsahai Memorial Hospital at Addis Ababa.

Professor Burrow was an able clinician whose services were much in demand in the north of England. His handsome figure, elegance of manner and gift for the apt illustration made him a popular teacher. The demands of practice left him little time for research, but he gave loyal and devoted service to the medical school of his adoption.

R. E. TUNBRIDGE

# Gravitation in Flat Space-time

by  
J. C. W. SCOTT

Defence Research Telecommunications  
Establishment, Ottawa, Canada

Einstein's general theory of relativity deals quite differently with gravitational and electromagnetic fields. What follows is a more symmetrical treatment. Unlike Einstein's theory, it predicts that the speed of light remains constant even when measured across a gravitational field.

A NEW antisymmetric tensor theory of gravitation has been developed which is a basic modification of my gravitokinetic theory<sup>1,2</sup>. In this theory space-time is always flat and energy and momentum are strictly conserved.

In analogy to the electrodynamics of moving media the field is now described by a source tensor and a force tensor. The relation between these two tensors depends on the local mass velocity and the direction of the vector potential. Thus the vector potential must be completely determined by the source distribution. If  $\gamma$  is the gravitational constant and  $\rho_0$  the rest density of mass the source tensor equations are

$$\square K^i = -4\Pi\gamma\rho_0 w^i \quad (1)$$

$$K^i_{;i} = 0 \quad (2)$$

which are completely determined when the boundary conditions at infinity are prescribed and impose the field equations

$$w_{ij} \equiv K_{i,j} - K_{j,i} \quad (3)$$

$$w^i_{;j} = -4\Pi\gamma\rho_0 u^i \quad (4)$$

Clearly both the field and its potential are propagated in empty space with the velocity of light.

The vector potential may be resolved into its invariant length  $\phi$  and its direction  $w_i$ . The gradient of its length is the generalized Newtonian field component  $G_i$ . Thus the field of a fixed and constant elementary source reduces to Poisson's or Gauss's law. We have

$$K^i \equiv \phi w^i \quad (5)$$

$$G_i \equiv \phi_{;i} \quad (6)$$

so that for a fixed elementary source

$$\nabla^2 \phi = 4\Pi\gamma\rho_0 \quad (7)$$

$$\nabla \cdot \mathbf{G} = -4\Pi\gamma\rho_0 \quad (8)$$

where  $\mathbf{G}$  is the spatial component of contravariant  $G^i$ .

The relation between the source field and the force field depends on what, in analogy to electrodynamics, we may call the constitutive equation. It defines the characteristic force field velocity  $v^i$  and may be written in the equivalent forms

$$w^a u_a w^i = \frac{1}{2}(u^i + v^i) \quad (9)$$

or

$$v^i = s^i j u_j \quad (10)$$

where

$$s^i j \equiv 2w^i w^j - g^{ij} \quad (11)$$

Its physical meaning is simply that the vector potential bisects the space-time angle between the local mass velocity  $u^i$  and  $v^i$ .

Both the source field  $w_{ij}$  and the relative force field  $G_{ij}$  may be broken into tensor components which depend respectively on the rotation of the vector potential and on its magnitude gradient

$$w_{ij} = \psi(w_{i,j} - w_{j,i}) - (G_i w_j - G_j w_i) \quad (12)$$

$$G_{ij} = w^a v_a \psi(w_{i,j} - w_{j,i}) - (G_i v_j - G_j v_i) \quad (13)$$

When the material velocity has the same direction as the vector potential  $u^i = v^i = w^i$  and  $G_{ij}$  reduces to  $w_{ij}$ . The force has the same form as the electromagnetic force with the rest density of mass replacing the charge density

$$f^i = -\rho_0 G^i u_j \quad (14)$$

Because of its low angular velocity the rotation dipole term of the gravitational field of the Sun is negligible. Assuming the solar field to be constant in time, special co-ordinates may be chosen in which the Sun is fixed at the origin. In these co-ordinates

$$K_i = (0, 0, 0, \psi) \quad (15)$$

$$u^i = (\lambda_u \mathbf{u}, \lambda_u), \quad v^i = (\lambda_v \mathbf{v}, \lambda_v) \quad (16)$$

$$\mathbf{u} = -\mathbf{v}, \quad \lambda_u = \lambda_v$$

and the curl of  $w_i$  may be neglected. If  $\mathbf{K}$  is defined by  $\mathbf{K} = \mathbf{v} \times \mathbf{G}$ , then

$$\mathbf{K} = -\mathbf{u} \times \mathbf{G} \quad (17)$$

and the solar force per unit volume reduces to the simple form

$$\mathbf{f} = \rho(\mathbf{G} + \mathbf{u} \times \mathbf{K}), \quad \dot{\rho} = \rho \mathbf{G} \cdot \mathbf{u} \quad (18)$$

Note that  $\rho$  is the relative mass density so that the force is proportional to the total mass as is required by the experiments of Eötvös and Dicke.

In terms of the vector distance from the Sun, after dividing by the density, the force becomes

$$\mathbf{F} = -\frac{\gamma s m}{r^2} (\mathbf{r}_1 - \mathbf{u} \times (\mathbf{u} \times \mathbf{r}_1)) \quad (19)$$

$$dm/m = -\gamma s dr/r^2 \quad (20)$$

where  $s$  is the mass of the Sun,  $m$  the accelerated mass and  $\mathbf{r}_1$  the unit radial vector.

The correct precession of the orbit of Mercury and the correct gravitational deflexion of a light ray are obtained from these equations in a straightforward manner.

In outline the reduction is as follows. The angular component is

$$2 \frac{\dot{r}}{r} + \frac{\ddot{\theta}}{\dot{\theta}} + \frac{\dot{m}}{m} = \gamma s \frac{\dot{r}}{r^2} \quad (21)$$

which has the integral

$$mr^2 \dot{\theta} = K e^{-\gamma s/r} \quad (22)$$

In terms of the rest mass  $m_0$  and the velocity  $U$  at perihelion we define the constant  $h$  by

$$\frac{1}{h^2} = \frac{m_0^2}{K^2} = \frac{1 - U^2}{R^2 U^2} e^{-2\gamma s/R} \quad (23)$$

where, when the velocity is the invariant velocity of light,  $1/h^2 = 0$ , the radial component reduces to

$$\frac{d^2 n}{d\theta^2} + n = \gamma s \left[ n^2 + \left( \frac{dn}{d\theta} \right)^2 + \frac{m^2}{K^2} e^{2\gamma s n} \right] \quad (24)$$

where  $n = 1/r$ , which leads to the orbital equation

$$\frac{d^2 n}{d\theta^2} + n = \gamma s \left\{ \frac{1}{h^2} [1 + 2\gamma s n] + 2 \left[ n^2 + \left( \frac{dn}{d\theta} \right)^2 \right] \right\} \quad (25)$$

The gravitational red-shift is a consequence of the conservation of energy and the proportionality of photon frequency to its energy.

Equation (20) has the integral

$$m = m_{\infty} e^{\gamma s/r} \quad (26)$$

which, because at the surface of the Sun  $\gamma s/r$  is of the order of  $10^{-6}$ , reduces to

$$m = m_{\infty} (1 + \gamma s/r) \quad (27)$$

and therefore to the corresponding dependence of photon frequency on distance from the Sun

$$f = f_{\infty} (1 + \gamma s/r) \quad (28)$$

The divergence of the energy tensor has the same form as its electromagnetic analogue for material media. The field energy, however, takes the place of Newtonian potential energy which like the latter belongs to the accelerated mass, just as much as does its kinetic energy or its rest energy and depends on its velocity. As in Newtonian theory it is a negative term in the positive total energy of the accelerated mass.

Thus this new theory extends the validity of Einstein's restricted theory of relativity to include the gravitational field on the same basis as the electromagnetic field and makes the complications of Einstein's general theory superfluous.

Moreover, new gravitational phenomena are predicted similar to electrodynamic phenomena. Thus a spinning mass should have a kinetic dipole moment analogous to the magnetic dipole moment of a spinning charge. In general, unless the velocity is large the kinetic component of the gravitational field will be difficult to measure because of the extreme weakness of the gravitational force.

A new radar test of relativity proposed by I. I. Shapiro<sup>3</sup> however, will definitely distinguish between this new theory and general relativity. Because in our theory the speed of light is unchanged by a gravitational field the transit time of a radar signal will depend only on the length of the path. Thus the theory predicts a null result from the experiment whereas a positive result is to be expected if Einstein's general theory is correct.

## Viral Transformation of Monkey Kidney Cell Cultures

by

ROSLYN WALLACE

Lederle Laboratories, Pearl River, New York

Simian tumour virus SV40 induces transformation of primary culture of cercopithecus monkey kidney cells. The cells become highly vacuolated, complement fixing viral antigen is formed and the cell become resistant to the cytopathic effects of the virus. It is probable that a persistent association develops between the cells and the virus genome.

THE simian virus SV40 induces tumours in hamsters<sup>1</sup> and transforms cell cultures of human, hamster, rabbit, mouse, swine, and bovine origin into cells with neoplastic features<sup>2</sup>.

Although the sera of rhesus and cynomolgous monkeys frequently contain antibodies to this virus, there is no present evidence that SV40 is oncogenic in monkeys. Rabson *et al.*<sup>3</sup> infected muscle, skin and testis cells from rhesus monkeys *in vitro* with SV40, and observed transformation several months later. Autologous implantation of the transformed cells failed, however, to produce tumours. Propagation of SV40 in cercopithecus monkey kidney (CMK) cells usually results in cytopathic changes leading to complete lysis of infected cultures<sup>4,5</sup>. Fernandes and Moorhead<sup>6</sup> established a strain (WGM-1) from CMK, and noted a gradual change in the susceptibility of the cells to the vacuolating effect of SV40 during serial culture. Low multiplicities of virus produced chronic infection in WGM-1 cultures; nuclear inclusions occurred in about 3 per cent of the cells, but no cytoplasmic vacuoles were observed. Morphological transformation occurred 15 weeks after infection.

This article reports the morphological transformation of primary cultures of CMK (PCMK) 6.5–7 weeks after infection with SV40, and although the transformed cell population was characterized by extensive cytoplasmic vacuolization, many of these cells were observed to undergo mitosis and amitotic polynucleate formation.

The SV40 strain used, the methods of preparing and maintaining PCMK cultures and the setting up of coverslip cultures for cytological investigation were as previously described<sup>7</sup>. Titrations of culture fluids for infectious virus were performed in PCMK cultures. In tests for traces of virus, 0.5 ml. of undiluted culture fluid or whole cultures, disrupted by freezing and thawing, were inoculated into

each of between five and eight tubes of PCMK culture. These were incubated at 37° C and observed for virus cytopathic effects over a period of 5 weeks.

Uninfected controls and transformed CMK culture were sub-cultured by dispersal of confluent cell growth with 0.01 per cent crystalline trypsin in Hanks balanced salt solution (pH 8.5). Aliquots of cell suspensions, diluted with LAPAGT growth medium containing 10 per cent cow serum<sup>8</sup>, were inoculated into other tubes or bottles. In comparative complement fixation tests and assay of susceptibility to superinfection with SV40, the cercopithecus monkey strain BSC-1 (ref. 9) was also used.

Complement fixed SV40 tumour antigen was measured by the microtechnique described by Huebner<sup>10</sup>. Antigen were 10 per cent suspensions of tissue cultured cells in veronal buffered diluent, frozen-thawed, and homogenized. For titrating antigens, a pool of sera from hamster bearing tumours induced with SV40 and free of virus was used at a dilution containing 8 units of SV40 tumour antibody.

The first transformed CMK strains were established from PCMK cultures in 16 × 150 mm tubes which had received 0.1 ml. of 10<sup>-4.0</sup> or 10<sup>-5.0</sup> dilution of frozen-thawed culture fluids with an SV40 titre of 10<sup>5.0</sup>–10<sup>6.0</sup> TCID<sub>50</sub>/0.1 ml. The fluids had been removed from cultures of human diploid fibroblasts 2 months after morphological transformation following exposure to SV40 (ref. 7), and were being titrated for infectivity in a series of 30 PCMK cultures. Of these cultures, fifteen inoculated and five uninoculated controls remained 1 month after infection and apparently normal cells were observed to repopulate many of the infected cultures which had earlier shown viral cytopathic effect. Six of these were selected and held together with five controls, for further observation

Growth medium was renewed twice a week. During the next 2 weeks, marked cytoplasmic vacuolation and some cell destruction occurred in all infected cultures, and three of them were lost by complete lysis. Viral titres of fluid at this stage ranged from  $10^{4.0}$  to  $10^{6.0}$   $TCID_{50}/0.1$  ml. About 6.5 weeks after infection, each of the surviving three cultures developed two or more dense foci of proliferating cells and marked acidity of the medium and, when sub-cultured, each produced a strain of cells capable of serial propagation. These were designated the *LCMK*-123 series. Sub-cultures were characterized by rapid acidification of the culture medium and extreme cytoplasmic vacuolation involving 60–70 per cent of the cells, many of which were also giant and polynucleated. Lobated, budding nuclei, similar to those in *SV*40-transformed human cells<sup>7</sup>, were prominent. No nuclear inclusions were apparent. Vacuolated cells were frequently seen in mitosis and undergoing amitotic nuclear divisions. A small percentage of the population evidenced severe nuclear fragmentation, and appeared to be degenerating (Figs. 1 and 2).

The growth rate and efficiency of *LCMK*-123 cultures remained relatively low during passages 1–24. About a million cells were required to initiate 8 oz. bottle cultures, which needed sub-division only once each week. At about the twenty-sixth passage, the growth rate and efficiency became accelerated. Cultures could be initiated with  $3 \times 10^6$  cells, and had to be sub-divided every 3 days. The numbers of cells with cytoplasmic vacuoles began to decrease at this time, and by the thirty-third passage vacuolated cells made up as little as 5 per cent of the population. *LCMK*-123 serial sub-cultures gradually lost virus. Fluids from the first to the third passage cultures contained  $10^2$ – $10^3$   $TCID_{50}/0.1$  ml., while the comparable value for the fourth passage was 10  $TCID_{50}/0.1$  ml. Fluids and cell homogenates subsequent to the sixth passage were usually negative, although an occasional culture yielded trace amounts of virus. On these occasions, one in seven *PCMK* cultures developed *SV*40 infection when inoculated with 0.5 ml. each of undiluted transformed tissue culture homogenate.

Non-infected control cultures were maintained for 8 months. Cells did not change as in infected cultures, and no virus was detectable. After three passages, sub-cultures failed to multiply and were discarded.

To determine whether transformation of *PCMK* cells by *SV*40 can be attributed to a property of virus propagated in human transformed cells, *SV*40 seed virus grown in cultures of *PCMK* and having a titre of  $10^{6.5}$   $TCID_{50}/0.1$  ml. was used to infect another group of *PCMK* tube cultures. Five weeks later, seven cultures containing cells surviving exposure to a  $10^{-6.0}$  dilution of virus and eight non-infected controls were renewed with growth medium. During the following 2 weeks, four of the

Fig. 2. *SV*40-transformed *LCMK*-123 cells, sixteenth tissue culture passage. Stained with haematoxylin. ( $\times 325$ .)

infected cultures were lost by complete viral cytopathic effects. Beginning seven weeks after infection, each of the three remaining *SV*40 cultures developed excessive acidity of the medium and colonies of transformed cell growth. On subsequent passage these strains, designated the *LCMK*-147 series, exhibited cellular characteristics similar to those described for *LCMK*-123 cultures except that the growth rate was rapid from the start and the numbers of vacuolated cells diminished earlier. Controls were maintained for 4 months, and showed none of the cellular changes seen in infected cultures.

To determine whether prolonged treatment with viral antiserum would accelerate virus loss from the transformed cultures, *LCMK*-147 cells from the second passage cultures were dispersed with trypsin, rinsed three times with five volumes of Hanks solution and exposed at a concentration of  $10^5$  cells/ml. to either Hanks solution or viral antiserum for 2 h at  $37^\circ$  C (rabbit antiserum was used, a dilution of 1:2000 of which neutralized 300  $TCID_{50}$  of *SV*40). Cells exposed to antiserum were further treated with culture medium containing 10 per cent antiserum for 2 weeks of continuous culture. Cultures treated with antiserum were negative for infectious virus after the fourth tissue culture passage, whereas those without antiserum yielded low levels of virus up to the sixty-fourth culture passage after infection. An occasional culture from the progeny of both cells treated with antiserum and untreated cells yielded traces of virus when tested at the tenth to twentieth passages, thus supporting the suggestion that the *SV*40 viral genome may be carried in a non-infectious state, and that maturation of virus occurs only rarely in an occasional cell<sup>11</sup>.

*LCMK*-123 and *LCMK*-147 cells proved to be resistant to the viral cytopathic effects of *SV*40. Replicate  $16 \times 150$  mm tubes were prepared from cultures, free of virus, of each of the transformed *LCMK* lines and also from the *BSC*-1 strain. Serial dilutions of *SV*40 grown in *PCMK* and with a titre of  $10^{6.0}$   $TCID_{50}/0.1$  ml. were inoculated into each tube. During a period of incubation of 4 weeks, the *BSC*-1 cells were destroyed by all dilutions of virus through  $10^{5.0}$ , whereas light microscopic examination revealed no evidence of viral cytopathology in the transformed *CMK* cells. The re-establishment of a persistent virus infection in *LCMK*-123 and -147 cultures was verified by the recovery of infectious virus from fluids for about 2.5 weeks after inoculation. Virus gradually disappeared, however, from all cultures in which superinfection had been attempted.

Tissue culture homogenates of both the transformed *LCMK* series were positive in complement fixation tests for the *SV*40 tumour antigen. *LCMK*-147 cultures at the eighth, eleventh and fourteenth passages reacted with hamster *SV*40 tumour antibody at dilutions of 1:64.

Fig. 1. *SV*40-transformed *LCMK*-123, fourteenth tissue culture passage. Stained with haematoxylin. ( $\times 75$ .)

while LCMK-123 cultures, at the twentieth, twenty-fifth, and twenty-eighth passages, reacted positively at dilutions of 1:32 to 1:64. None of the transformed LCMK cell homogenates reacted with normal hamster serum, and antigens prepared from uninfected CMK or from BSC-1 cells were negative for the SV40 tumour antigen.

SV40 virus in PCMK cells normally enters a replicative cycle ending in complete destruction of the cells rather than the morphological transformation reported here after low doses of virus. Fernandes and Moorhead<sup>6</sup> produced a carrier state in WGM-1 cells infected with SV40, and found their strain not to be susceptible to the vacuolating effect of the virus. They noted transformation 15 weeks after infection, after which there was a lytic phase correlated with the percentage of cells with nuclear inclusions and the viral antigen appeared in the nucleus.

In the present investigation, PCMK cells surviving the lytic effect of low virus doses exhibited marked cytoplasmic vacuolation for 3 weeks before and for several months after transformation. Although 60–70 per cent of the cells contained numerous large vacuoles, many of these were observed to undergo mitosis and to form amitotic polynuclei. Cytological investigations of SV40 infections in patas and cercopithecus monkey kidney cultures<sup>4,5</sup> have indicated an apparent lack of correlation between the development of nuclear inclusions and cytoplasmic vacuolation; each abnormality has been seen without the other, and they appear to be separate phenomena. Our findings indicate that cytoplasmic vacuolation is not associated with the release of a large amount of infectious virus, nor invariably followed by cell destruction. A lytic phase did not follow transformation of the PCMK cells, and although a small percentage of cells with nuclear inclusions may have been present, they were not seen in the transformed populations examined.

It is unlikely that the development of transformed cell lines after SV40 infection of PCMK cultures is the result of the overgrowth of a cell contaminant. The unique cytoplasmic vacuolation of polynucleated cells in LCMK-123 and -147 cultures is a morphological characteristic unlike any observed in cell lines at present maintained in these laboratories, and has not been apparent in human and hamster cells infected *in vitro* with SV40. At the time of these experiments, the only other tissue culture lines in this laboratory were those derived from hamster tumours induced *in vivo* by SV40 and highly tumorigenic for the weanling hamster. In contrast, neither LCMK-123 nor -147 produced tumours in weanling hamsters inoculated subcutaneously in doses of 10–20 million cells.

In the LCMK-123 and -147 lines, the presence of complement fixed SV40 tumour antigen, resistance to viral cytopathic effects of SV40, and the characteristic cytoplasmic vacuolation in a large percentage of the transformed cells point toward some persisting effect of an intimate association between the cells and the SV40 genome, and suggest that the cells were transformed because of this association. Little is known of the mechanisms in cell interactions with cytolytic viruses that can lead to a neoplastic event. The transformation of primary CMK cells by SV40 as described here may have been the result of a gradual change in resistance to the cytolytic action of the virus by certain cells, or to selection of pre-existing cells which differed in their response to infection. Interferon is produced by CMK cells infected with SV40 (ref. 12) and Isaacs<sup>13</sup> has postulated its promoter action in tumour formation by stimulation and selection of cells which obtain their energy by glycolysis. As a result of a repressor action in certain cells of an initial step in the viral vegetative cycle, the virus might enter a sub-viral state in the nucleus of the cell. Stimulation of cell multiplication by the renewal of cultures with growth medium could lead to genetic alteration after intimate contact with viral genome during a susceptible period in the replicative cycle of the cells.

Although interactions leading to cell transformation may be rare in cell populations undergoing viral cytopathic changes, the observations reported here indicate that these events are sufficiently frequent and reproducible in the SV40-CMK system to allow experimental investigation.

I thank Mrs. Susan Kulina for technical assistance and Mrs. E. Osborn for her help in the preparation of this article.

## A Carrier State of Lymphocytic Choriomeningitis Virus in L Cell Cultures

by

F. LEHMANN-GRUBE

Hygiene-Institut der Universität,  
Marburg-Lahn, Germany

The establishment of a carrier state for lymphocytic choriomeningitis virus in mouse L cells, without antibodies or a requirement for interferon production, indicates that other self-regulatory mechanisms can balance the simultaneous synthesis of new cellular and viral material.

KNOWLEDGE concerning the basic mechanisms involved in lymphocytic choriomeningitis (LCM)—a virus disease of the mouse<sup>1</sup>—is still scanty despite numerous efforts for more than 30 years<sup>2</sup>. The lack of an *in vitro* cell system, with which to study the interaction between host and parasite at the cellular level, appears to be the main cause of this deficiency. Efforts to fill this gap have indicated that a variety of different cells can support the multiplication of the virus; others are less suitable (unpublished results). This report is concerned with

experiments designed to obtain an LCM virus-carrier state in L cells<sup>3</sup> (kindly supplied by Prof. W. Schäfer).

The L cells were routinely grown in "milk dilution bottles", using Eagle's basal medium (EBM)<sup>4</sup> with no essential amino-acids<sup>5</sup>, supplemented with 10 per cent heated calf serum (CaS). For experimental purposes the cells were seeded into square screw-capped tablet bottles with a surface area of 21 cm<sup>2</sup>. Cells were enumerated by counting crystal violet stained nuclei, released after incubation at 37° C, with a solution of 0.1 per cent

Fig. 1. Growth of LCM virus, strain WE<sub>3</sub>, in cultures of L cells. ●, Multiplicity of infection, 0.1; ○, multiplicity of infection, 0.0001.

'Tween 80' in 0.1 molar citric acid; this is a modification of the method developed by Sanford *et al.*<sup>6</sup>. The WE<sub>3</sub> strain of LCM virus, derived from the WE strain<sup>7</sup>, was provided by Professor W. Scheid. Some of its properties have already been reported<sup>8,9</sup>. Seed virus was prepared from lungs and spleens of infected guinea-pigs<sup>8</sup>. The Armstrong strain<sup>10</sup> was obtained from the American Type Culture Collection. A pool was prepared from mouse brains 5 days after intracerebral infection<sup>8</sup>.

For virus assay, decimal dilutions were made up in balanced salt solution (BSS)<sup>11</sup> containing antibiotics. Portions of 0.03 ml. were inoculated intracerebrally into 4–5 week old mice (five animals per dilution). The 50 per cent lethal dose (LD<sub>50</sub>), based on deaths occurring between the fifth and fourteenth day after infection, was calculated according to Fazekas de St. Groth<sup>12</sup>. The titres presented in the growth curve (Fig. 1) represent 50 per cent infectious doses (ID<sub>50</sub>), determined as previously described<sup>8</sup>. Intracellular virus was set free by means of an ultrasonic drill. Complement-fixing antigen was assayed in tubes using antiserum from a rabbit immunized with monkey kidney-grown virus. Host-specific or non-specific reactions were ruled out by the incorporation of suitable controls. The vesicular stomatitis virus (VSV), strain 'Indiana', was obtained from the American Type Culture Collection. A pool was prepared by inoculating monolayer cultures of L cells using EBM supplemented with 1 per cent heat-inactivated CaS for maintenance. As soon as the cytopathic effect had developed in essentially all cells (which was the case little more than 1 day later) the media were pooled, centrifuged free of cell debris at 4° C, dispensed in ampoules, and stored at –60° C. Titres were determined by inoculating 0.1 ml. of virus, diluted in log<sub>10</sub> 0.5 steps, into L cell tube cultures containing 0.9 ml. of fresh maintenance medium. Five tubes were used for each dilution. Final titres based on the cytopathic effect on the seventh day were calculated<sup>12</sup> and expressed as ID<sub>50</sub>/ml. Tests for the presence of interferon in media from infected L cells were carried out in homologous cell cultures essentially as described by Sellers and Fitzpatrick<sup>13</sup>. VSV was used as the challenging agent. Media were rendered non-infective by ultracentrifugation followed by either dialysis for 24 h against a pH of 2 or by heating at 37° C for 50 h.

After infection of L cell cultures with either high or low doses, newly replicated virus appeared within 24 h and reached maximum titres on days 3 and 4, depending on the initial inocula used (Fig. 1). Thereafter, the virus content in the medium dropped. Throughout the period of observation, infected cultures were morphologically similar to the controls. Furthermore, counts performed repeatedly showed that there was no change in the number of cells present.

The establishment of carrier cultures was achieved in the following way. Bottle cultures of L cells were washed three times with BSS and infected with 0.5 ml. LCM virus, strain WE<sub>3</sub>, at a multiplicity (mouse ID<sub>50</sub> per cell) of about 0.1. After a period of adsorption at 37° C for 60 min, 4.5 ml. of growth medium was added. Forty-eight hours later the media from two cultures were pooled and centrifuged in the cold. The supernatant was dispensed into ampoules and stored at –60° C, until virus titrations were carried out in mice. Cells were washed three times with BSS, dispersed with 0.05 per cent trypsin, diluted to contain about 10<sup>5</sup> cell/ml. with growth medium, and seeded into new culture vessels. At the same time two parallel cultures were prepared with 'Tween'-citric acid to be counted the next day. When the cell sheets were almost complete, that is, 2–3 days after they had been seeded, the cultures were rinsed three times and overlaid with 5 ml. of fresh medium. Again, 48 h later, media from two cultures were pooled and stored in ampoules for assay. The cells were sub-cultured as already described and the cell number was determined from parallel cultures. Results from ten such passages together with uninfected controls are depicted in Fig. 2. The multiplication of the cells was significantly affected by the virus only after the first sub-cultivation. This phenomenon, which has been observed regularly (see also Fig. 4), was accompanied by a cytopathic degeneration affecting about half the cells on the glass. While it is possible that cells infected with virus were still slightly injured during the following two sub-passages (though when compared with the controls there were no visible alterations) no significant differences could be observed thereafter. An interesting, though unexplained, feature of this experiment was the fluctuation with time (or passage numbers) of the amount of infectious virus released into the medium, a fluctuation which was both regular and extensive. Comparable changes of the virus content in the medium of lymph-node cultures infected with LCM had been seen by Traub<sup>14</sup>.

Table 1 summarizes the results of virus titrations from different levels of sub-cultivation. It can be seen that the increases and decreases of virus yields which are so strikingly obvious in Fig. 2 extended to at least the fifteenth cell passage. Later on, however, there appears to be less irregularity of virus release from persistently infected cells (Table 1). (It should be noted that inactivated calf sera, as well as sera from animals representing a variety of other species, have never been found to contain factors which inactivate virus, even if tested undiluted.) While there is no doubt that L cells carrying LCM virus behave very much like their normal counter-

Fig. 2. Initiation of L(WE<sub>3</sub>) carrier cell cultures. Numbers of cells per culture (round symbols) and yields of virus per culture medium (columns) of the first ten passages are represented. ●, WE<sub>3</sub>-infected cultures; ○, control cultures.

parts, small differences would have escaped notice with the techniques used. Of all possible ways to assess the overall metabolic state of a cell *in vitro* the determination of its growth rate appears to be the most direct and, at the same time, the most informative procedure. Cells from carrier and from control cultures, respectively, were dispersed by the action of trypsin. After enumeration in a haemocytometer, they were diluted with growth medium to contain 5,000 cells/ml. Five ml. was seeded into 5 cm Petri plates, which were incubated under 5 per cent carbon dioxide in a humidified incubator at 37° C. At regular intervals, three dishes were removed and the cells were counted as already described. The results from three such experiments performed with cells corresponding to the thirty-first, the thirty-third and the thirty-fifth passage, respectively, of which one is presented in Fig. 3, can be summed up as follows: the doubling time of normal *L* cells under our experimental conditions was always close to 13 h. The doubling time for the carrier cells was possibly slightly longer. A difference, however, was seen in two of three comparative trials only and did not reach statistical significance in the individual case. Thus, if any difference exists, it is small.

The question to be answered next concerned the fluctuation of infectious virus titres in the culture media

Fig. 8. Comparison of the multiplication of  $L(WE_3)$  cells (●—●) and *L* (normal control) cells (○---○). (Arrows denote change of medium.)Fig. 4. Superinfection of  $L(WE_3)$  cell cultures with isologous ( $WE_3$ ) and homologous (Armstrong) strains of LCM virus. (Compare with Fig. 2.) ●,  $WE_3$ ; ■,  $WE_3 \rightarrow WE_3$ ; ▼,  $ARM \rightarrow WE_3$ ; ○, CO; □,  $WE_3 \rightarrow CO$ ; ▽,  $ARM \rightarrow CO$ .

at different passages (see Fig. 2 and Table 1). The possible role of interferon-like substances or of homologous interference was investigated. As regards interferon, it suffices to state that neither cells 3 or 7 days after primary infection with  $WE_3$  virus nor carrier cells corresponding to the nineteenth level of cell passage released such a substance; the media, even when tested undiluted, did not noticeably reduce the susceptibility of *L* cells to VSV. Carrier cell cultures at the sixth level of passage were superinfected with the isologous ( $WE_3$ ) and a closely related (Armstrong) virus. Fig. 4 shows that the virus yield after 48 h was low and not altered by the superinfection with either virus. The control cultures infected under identical conditions released large amounts of progeny virus. A further passage of these cells confirmed the observation already reported that infected cells passaged once exhibited a cytopathic effect and a reduced cellular multiplication. Again, superinfected cells could not be distinguished from both types of controls. Thus, while there is marked homologous interference, interferon would not seem to have been responsible for the observation reported here.

The possibility was also considered that the periodically occurring reduction of the infectivity might result from the intermittent production of virus-like but non-infectious particles causing a phenomenon similar to that described by von Magnus for myxoviruses. For want of a haemagglutinin test, the media of all passages listed in Table 2 were investigated for virus-specific material which would fix complement with a hyper-immune rabbit serum. The results presented in Table 2 show that only traces were found in some fluids. Homologous interference was tested by titrating VSV in persistently infected *L* cells in parallel with non-infected controls using five tube cultures for each 3.16-fold dilution step. The results of three representative experiments are given in Table 2. Neither the time of appearance of the cytopathic effect due to VSV nor the final titre on the seventh day was influenced by the carrier state of the cells. Thus while superinfecting identical or similar viruses were inhibited to the same extent as the carrier virus, interference against a heterologous virus could not be detected.

\* Three cultures assayed.

These observations partly confirm and extend those by Wagner and Snyder<sup>15</sup>, who have mentioned persistent infection of *L* cells with the LCM virus in the absence of resistance-promoting factors in the medium. They contrast with these authors' finding, however, in that the carrier cultures "exhibited moderately increased resistance to superinfection with vesicular stomatitis virus". Traub and Kesting<sup>16</sup>, who worked with LCM-infected mouse lymph-node cells cultivated on glass, reported marked homologous interference but no suppression of the susceptibility to Eastern equine encephalitis and vesicular stomatitis viruses. Mims and Subrahmanyam<sup>17</sup> used mouse peritoneal macrophages and fibroblasts infected with LCM. Superinfection with the isologous virus did not change the proportion of cells containing antigen as revealed by fluorescing antibodies. As judged by the same criterion, LCM-infected macrophages were slightly resistant to ectromelia virus. Fibroblasts, on the other hand, were fully susceptible to the encephalomyocarditis and Semliki forest viruses. In these investigations interferon was not detected in cultures of cells infected with LCM virus.

In conclusion, cultures of cells infected with LCM are resistant to superinfection with the isologous agent or related strains; they do not release interferon and are, as a rule, not refractory to heterologous viruses. Of the many examples of persistent viral infection of cultivated cells which have been described in the past, more than one has been shown to exhibit similar properties. In fact, not one feature described here is uniquely associated with our carrier cultures. What sets the *L* (LCM) system apart is the faculty of the LCM virus not only to initiate and maintain a persistent infection in cells *in vitro*, but also to induce a status *in vivo*, that is in mice, which is similar in all major aspects. There the same criteria hold and can be listed as follows: (a) persistent viral infection in the absence of antibodies<sup>18-21</sup>; (b) few outward signs of illness and no major pathological alterations of the mouse despite continuous virus multiplication<sup>22-24</sup>; (c) the absence of interfering soluble factors in the tissues of LCM-infected mice<sup>15,17,21,25</sup>; (d) interference with superinfecting identical or closely related strains<sup>17,26</sup>; (e) lack of interference with at least two heterologous viruses, that is ectromelia<sup>17</sup> and yellow fever<sup>21</sup>. (The slight but undoubtedly significant resistance of LCM carrier mice

towards the EEE virus<sup>15,25,26</sup> is also exhibited by mice actively immunized with the LCM virus<sup>25</sup>. This type of refractoriness to a superinfecting virus, therefore, seems to result from some mechanism other than viral interference.)

This overall similarity of the properties of persistently infected mouse cell cultures as compared with the LCM carrier mice is indeed striking. While our primary objective is the immunological relationship between LCM virus and its natural host, a detailed knowledge of the events following the infection of cells maintained under defined conditions appears to be a prerequisite. With this in mind experiments are now being conducted to investigate the interaction of the LCM virus with its host on the cellular level, taking advantage of the availability of an *in vitro* model as has been described.

I thank Miss R. Tees for her excellent technical assistance in this work, which was supported by the Deutsche Forschungsgemeinschaft.

## Competence in *Bacillus subtilis* Transformation System

by

FRANK E. YOUNG

Division of Microbiology,  
Scripps Clinic and Research Foundation,  
La Jolla, California

Immediately after uptake of tritiated DNA into the bacterial cell, the label is located adjacent to the cell wall. Cell fractionation studies indicate that the newly acquired DNA is bound to the cytoplasmic membrane, not the cell wall.

THE first step in the process of genetic transformation of cells by deoxyribonucleic acid involves a modification of the cell to permit binding of DNA. The mechanism by which cells develop the capacity to incorporate DNA (competence) still remains to be defined in molecular terms. As long as 20 years ago McCarty *et al.*<sup>1</sup> suggested that "it is not unreasonable to suppose that less extensive reversible alterations at specific sites of the surface of the pneumococcal cells can result from enzymatic actions and that these alterations make possible the adsorption or penetration of specific deoxyribonucleic acid". Extracellular activating factors have been identified in the pneumococcal<sup>2</sup> and streptococcal transformation systems<sup>3</sup>.

In *Bacillus subtilis* there are differences in the chemical composition and enzyme activity of cell walls of the highly transformable strain and mutants which are blocked in the capacity to incorporate DNA<sup>4,5</sup>. The relationship between the mode of action of the activating factors described in the pneumococcal and streptococcal transformation systems and the chemical and enzyme modifications in highly transformable strains of *B. subtilis* remains to be elucidated.

The present work was initiated to ascertain by morphological and chemical methods the location of donor DNA in the recipient cell immediately after irreversible uptake during the process of genetic transformation. The data

demonstrate that the DNA is bound to the surface of the cell in a DNase-insensitive and lysozyme-insensitive form most frequently in association with structures resembling fore-spores. These observations indicate that the DNA could be bound to the cytoplasmic membrane after transformation.

Competent cultures of *B. subtilis* were obtained by growing the highly transformable strain for 5 h in growth medium and for 60–75 min in the transformation medium at 36° C with vigorous aeration as described previously<sup>4</sup>. In these conditions transformation frequencies of 1 per cent to 4 per cent could be obtained for a number of genetic traits. Tritiated DNA was prepared by growing an adenine auxotroph or thymidine auxotroph on adenine-<sup>3</sup>H and thymidine-<sup>3</sup>H respectively<sup>4</sup>. The competent cultures used for the morphological experiments were incubated for 30 min at 35° C with DNA (2.5 µg/ml. specific activity, 1,310 c.p.m./µg of DNA) with vigorous aeration. The reaction was terminated with DNase (50 µg/ml.), and the cells centrifuged at 8,000 r.p.m. for 5 min at 4° C. The pellet was resuspended in cold minimal growth medium and then centrifuged again. This process was repeated twice to ensure the removal of degraded DNA and reversibly bound DNA. The cell pellet was then fixed in osmic acid<sup>6</sup>, processed as described by Kellenberger *et al.*<sup>7</sup>, embedded in methacrylate and in 'Epon' and sectioned on a Porter Blum microtome. Some of the sections were coated with Kodak nuclear track emulsion, stored at room temperature for 2 weeks in the dark and then processed as described by Salpeter and Bachmann<sup>8</sup>. In other experiments thick sections were examined directly. Two predominant forms exist in the population at the time of maximal competence (Fig. 1). One type (A in Fig. 1) has a large pale structure at one end of the cell which is surrounded by a double membrane. This structure in these thick sections is probably analogous to the ovoid form of presporulation (stage III) described by Ryter in a detailed morphological investigation of sporulation in *B. subtilis*<sup>9</sup>. Other cells (B in Fig. 1) are still in the vegetative phase of growth. Approximately 20 per cent of the cells have tracks produced by the disintegration of tritiated DNA. In 88 per cent of the cells examined the disintegration track of tritium was located adjacent to the cell wall–cytoplasmic membrane complex (Fig. 2). These tracks were most frequently seen in association with the pale structures tentatively identi-

Fig. 1. Heterogeneity of a competent population of *B. subtilis*. Cell A is a cell with a large elliptical structure suggestive of a fore-spore. Cell B is a vegetative cell. (× 44,000.)

Fig. 2. Autoradiography of *B. subtilis* incubated with tritiated DNA. Disintegration tracks are indicated by the arrows. (× 48,000.)

fied as fore-spores. It is not possible to determine whether the disintegration tracks were related primarily to the cell wall, cytoplasmic membrane or fore-spore membranes.

To ascertain whether the newly acquired DNA was associated with the cell wall or cytoplasmic membrane, lysozyme was added to cultures of transformed cells at various intervals after the irreversible incorporation of DNA. Lysozyme solubilizes almost all of the teichoic acid in the cell wall. The sucrose in the medium stabilizes the protoplasts and prevents their lysis<sup>10</sup>. The addition of lysozyme resulted in greater than 99–96 per cent reduction in the cells which can withstand osmotic shock (residual viable count of protoplasts diluted in water). Table 1 shows that the amount of radioactive DNA in the supernatant liquid and the pellet is similar in the lysozyme-treated and control cultures. Less than 25 per cent of the radioactivity in the supernatant liquid is acid precipitable. Similar results were obtained with cells which were killed with ultra-violet light and by heating before the addition of lysozyme, and so the release of radioactive fragments of DNA during the incubation period with lysozyme apparently results from a transfer of fragments of DNA from the cell to the extracellular medium. The loss of radioactive DNA is not confined to cells incubated in the sucrose medium. A similar loss of radioactive fragments of DNA occurs during incubation of transformed cells in transformation medium. Again only a small portion of this radioactivity is acid precipitable. Lysozyme, therefore, does not liberate a significant amount of the newly acquired DNA immediately following transformation.

Table 1. LOCATION OF TRITIATED DNA AFTER IRREVERSIBLE INCORPORATION IN *B. subtilis*

Time of incubation (min)	Supernatant liquid		Pellet	
	SC (c.p.m./ml.)	LC (c.p.m./ml.)	SC (c.p.m./ml.)	LC (c.p.m./ml.)
0	273	255	690	828
30	152	142	560	523
60	159	177	568	503
120	179	139	395	386
180	122	133	326	308

A competent culture of *B. subtilis* 168 I-C<sup>+</sup> was exposed to tritiated DNA (0.13 µg/ml. specific activity 10<sup>5</sup> c.p.m./µg) for 15 min at 37° C. The reaction was terminated by DNase (10 µg/ml.) and the cells sedimented at 8,000 r.p.m. at 4° C. The pellet was washed three times with transformation medium, resuspended in transformation medium, divided into five aliquots, and incubated for 0, 30, 60, 120 and 180 min at 35° C. These cultures were centrifuged and resuspended in 0.5 molar sucrose<sup>10</sup>. Lysozyme (200 µg/ml.) was added to half of the cultures (LC), the other half received an equal volume of 0.5 molar sucrose (SC) and served as the control. After 20 min at 37° C the cultures were centrifuged at 4° C for 10 min at 9,000 r.p.m. The radioactivity of the supernatant liquid and the pellet was determined in a Packard 'Tri-Carb' scintillation spectrometer.

A more extensive release of radioactivity was observed with lysozyme from cells which had incorporated DNA-<sup>32</sup>P than was noted in the present investigation<sup>11</sup>. Two aspects of the previous investigation must be considered carefully. First phosphorus-32 rather than DNA-<sup>3</sup>H was used as the donor DNA. Second, it is not known whether the radioactive phosphorus released by lysozyme was in macromolecular DNA, oligonucleotides, or inorganic phosphorus. In *Pneumococcus* approximately 50 per cent of the total radioactivity incorporated during transformation exists initially as low molecular weight fragments<sup>12</sup>. One-quarter to one-third of this radioactivity is in inorganic phosphorus<sup>12</sup>, and so the re-utilization of labelled inorganic phosphorus in cell wall biosynthesis could produce teichoic acid labelled with phosphorus-32 which would be released by lysozyme. Thus, the greater release of radioactive material in the study of Miller and Landman<sup>11</sup> may be a result of the combination of transfer of degraded DNA to the extracellular medium (as noted in the present investigation) and the release of teichoic acid labelled with phosphorus-32.

During the penetration of DNA into the cell, the cell wall must be transversed. There are differences in chemical composition of the cell walls of highly and poorly transformable strains. Not only do the highly transformable strains contain more galactosamine than the poorly transformable strains so far investigated<sup>4</sup>, but the galactosamine content of the cell wall increased with growth, reaching a maximum at the time of maximal competence<sup>13</sup>. Galactosamine is isolated with the teichoic acid fraction of the cell wall<sup>5</sup>, and so it is possible that an increased substitution of galactosamine on terminal phosphorus groups could decrease the net negative charge of the cell wall and facilitate penetration of DNA. The modification of the cell wall by its indigenous autolytic enzyme *N*-acyl muramyl-L-alanine amidase might produce focal relaxation and gaps in the cell wall and thus facilitate the penetration of DNA<sup>5</sup>. Two observations strongly indicate that the initial irreversible complex between DNA and the cell does not result from binding of DNA to the cell wall. First, the irreversibly bound DNA cannot be stripped by lysozyme. Second, irreversible complexes cannot be formed between DNA and cell walls or DNA and cell wall polymers. Furthermore, cell wall polymers do not inhibit transformation. The data presented in this communication, however, cannot rule out a complex between the DNA and a lysozyme insensitive portion of the cell wall.

The capacity to sporulate is observed to be frequently associated with competence<sup>14,15</sup>. On the other hand, mutants have been isolated which are blocked in some aspect of sporulation, but are still susceptible to transformation<sup>16,17</sup>. In the absence of detailed morphological work on these organisms it is impossible to ascertain whether the early stages of sporulation occurred. On the basis of the frequent association of the capacity to sporulate with competence, and the morphological observations that the DNA was associated with cells containing structures resembling fore-spores, it is possible that the DNA is segregated after irreversible binding to the cytoplasmic membrane into the fore-spore and thus exists in a form which is not in equilibrium with the remainder of the genome of the cell. This process of segregation of DNA during fore-spore formation could be the driving force for uptake of DNA in a fashion analogous to that proposed for the replication of DNA during conjugation<sup>8</sup>. The subsequent failure of the sporulation processes to go to completion in minimal medium may produce a reversion to vegetative growth and permit complete recombination and expression of the newly acquired genetic information.

## Metabolic Pathways of Red Blood Cell Copper in Normal Humans and in Wilson's Disease

by

PETER Z. NEUMANN  
MERVIN SILVERBERG

Liver Function Unit,  
The Montreal Children's Hospital,  
Montreal, Quebec, Canada

One of the symptoms of Wilson's disease (hepatolenticular degeneration) is an increased output of copper in the urine. This now seems to be linked with a defect in the binding of copper to amino-acid in the blood.

In recent years it has become increasingly apparent that the proper balance of the biologically available metals, such as copper, is necessary for the efficient metabolism and growth of human and animal organisms. Copper deficiency rarely occurs in humans<sup>1,2</sup>, and despite its widespread use in everyday life, poisoning by this metal is as unusual as its deficiency<sup>3</sup>. We know only one

hereditary abnormality, Wilson's disease (hepatolenticular degeneration; HLD), in which the inherited defect in the regulation of copper metabolism results in a progressive, fatal copper toxicity<sup>4</sup>.

Copper is essential for erythropoiesis in most mammalian species. There is a well established association between the shortened survival time of erythrocytes of

copper deficient pigs<sup>5</sup>, and anaemia associated with dietary copper deficiency in dogs and man<sup>2,6</sup>. It seems that the state and amount of copper in erythrocytes are important in maintaining the integrity of the cells.

Previous investigators showed that copper enters erythrocytes both *in vivo*<sup>2</sup>, after an oral or intravenous administration of copper, and *in vitro*<sup>7</sup>. It is present in red blood cells both as a minor diffusible and a major non-dialysable fraction<sup>8</sup>. The studies of Bush *et al.* showed the probable existence of these labile and stable copper pools in erythrocytes of normal individuals. It has been suggested that the stable pool is identical with erythrocytein, but the chemical nature of the labile pool has never been described<sup>9</sup>.

The copper enters erythrocytes from the plasma compartment<sup>9</sup>, and it could in theory originate from copper bound either to ceruloplasmin or albumin. Copper has never been shown to be dissociated from ceruloplasmin at physiological pH (7.4) either *in vitro* or *in vivo*<sup>10</sup>, and it was thought until recently that the transport source of copper is the albumin-bound fraction<sup>1,11</sup>. The latter was presumed to be freely diffusible across semi-permeable membranes, red blood cell membrane, glomerular capillaries, placenta<sup>12</sup> and blood brain barrier<sup>13</sup>. A previous report by one of us<sup>14</sup> seems to indicate that there is a small fraction of plasma copper, bound to amino-acids, which may be the physiologically important transport form of copper in blood, capable of diffusing across cell membranes. We have also shown that amino-acids, particularly histidine, facilitate the active transport of copper-64 in several mammalian tissues, for example, rat liver slices, rat kidney slices, Ehrlich mouse ascites carcinoma cells<sup>15</sup>, and human liver slices<sup>16</sup>.

It may therefore be postulated that the physiologically active transport form of copper is bound to amino-acid, which may have an important function in the transport of copper between the plasma and erythrocyte compartments.

The few investigators in the past who have studied the state of copper in red blood cells in patients with Wilson's disease found it to be not significantly different from normal human controls<sup>6,17</sup>. These cases were, however, under treatment with copper-chelating agents at the time of study and the results might have been affected by this.

The present article describes the rate of uptake, the role of amino-acids in uptake, the nature of transport, the chemical nature of the labile pool, and the dynamics and distribution of copper-64 in erythrocytes of an untreated 12 year old boy suffering from Wilson's disease and his 11 year old normal brother. The sibling was considered to be normal because of a normal serum ceruloplasmin and an abnormal rate of incorporation of copper-64 into ceruloplasmin *in vitro*.

Both *in vivo* and *in vitro* studies were carried out using cupric-64 acetate of high specific activity (10–20 mc./ $\mu$ g copper). All samples were counted in a well type scintillation counter of 5 per cent efficiency for copper-64. Standards were counted twice daily, and all counts were corrected for radioactive decay. In all procedures, copper-free needles, syringes and test-tubes were used.

The following experiments were carried out.

(1) *In vivo* uptake of copper-64 by erythrocytes. A normal subject and a patient with Wilson's disease (both males, 11 and 12 years of age, respectively) were given a single intravenous dose of 0.5 mg (1 mc.) of copper-64. The radioactivity was determined serially in 5 ml. portions of whole blood and 2 ml. of plasma. The samples were drawn through an indwelling catheter at 5, 10, 20 and 30 min and 1, 2, 3, 4, 5, 7, 10, 12, 18, 35, 42, 58, 61 and 63 h after injection of the radiocopper.

The radioactivity in erythrocytes was calculated directly by pipetting exactly 5 ml. of blood into counting vials, which were centrifuged for 3 min at 3,000 r.p.m. at 5°C. The plasma was discarded, the cells were washed

twice with ice-cold physiological saline, recentrifuged and counted immediately.

Results were no different when the red blood cell activity was calculated as the difference between plasma and whole blood activity. Haematocrits were determined in random samples, and showed no significant difference on any occasion.

On the first and second day of the experiment, blood was taken from both subjects and the total erythrocyte copper content was determined by the method of Eden and Green<sup>18</sup>.

During the experiment, both experimental subjects were kept on a low copper diet, containing less than 1.0 mg copper per day.

(2) *The effect of amino-acids on the transfer of copper through a semi-permeable membrane.* A 4 g per cent purified human albumin solution in Krebs-Ringer-bicarbonate (KRB) buffer of pH 7.4, with added copper-63 and copper-64 acetate, was dialysed through a semi-permeable membrane against the same albumin solution with no added copper at 37°C with constant shaking.

The twenty naturally occurring amino-acids were added to another portion of the same albumin solution in physiological concentration<sup>19</sup> and the same experiment was carried out.

The percentage of copper-64 dialysed across the semi-permeable membrane was determined serially up to 24 h.

Similar experiments were carried out using fresh serum of a normal donor and of the patient with Wilson's disease. A portion of this serum was first dialysed against five changes of five times the volume of Krebs-Ringer-bicarbonate buffer at pH 7.4 for a period of 3 h each, in order to dialyse out all diffusible constituents of serum, including amino-acids. Following this "predialysis", a mixture of copper-63 and copper-64 acetate was added to the portions of dialysed serum, in amounts to achieve an albumin : copper molar ratio of 1 : 2, and were then dialysed against either the "native" or "pre-dialysed" serum with no added copper.

(3) *The effect of amino-acids on uptake of copper-64 by red blood cells (RBCs).* In order to determine the effect of amino-acids on the uptake of copper-64 by RBCs from plasma, 300 ml. of blood was taken from a healthy donor, 24 h before the experiment, and collected in plastic bags containing 15 ml. of acid-citrate-dextrose solution. The erythrocytes were separated and discarded. The plasma was divided into two aliquots. One was stored at 5°C, the other was dialysed against five changes of five times volume of Krebs-Ringer-bicarbonate solution of pH 7.4 also at 5°C, in order to dialyse out all amino-acids from the plasma.

On the day of the experiment an additional 300 ml. of blood was taken from the same donor, and the red blood cells separated and kept at 5°C for less than 3 h.

5  $\mu$ c. of copper-64 (in 4  $\mu$ moles concentration) was added to 30 ml. portions of native and pre-dialysed plasma, and 0.3 ml. L-histidine was added in equimolar (4  $\mu$ moles) concentration to the different dialysed portions of plasma. This medium was then adjusted to pH 7.4 with 0.1 normal sodium hydroxide. To each 30 ml. portion of plasma 20 ml. of fresh packed RBCs were added. 1 ml. portions were taken at this time to determine the total activity in each sample.

2 ml. portions were withdrawn after 10, 20, 30, 60, 120, 180 and 200 min of incubation in the Dubnoff shaker at 37°C, in an atmosphere of 95 per cent oxygen and 5 per cent carbon dioxide. The erythrocytes were separated by centrifugation at 5,000 r.p.m. for 5 min, washed twice in ice cold 0.9 per cent sodium chloride and assayed for radioactivity. The uptake of copper-64 was expressed as c.p.m./ml. packed cells. In a similar experiment, a double label technique was used by adding <sup>14</sup>C-L-histidine of 0.5  $\mu$ c. activity to determine the possible uptake of histidine into red blood cells with the labelled copper. The change in the plasma level of <sup>14</sup>C-L-histidine was

Fig. 1. The *in vivo* labelling of erythrocytes by copper-64 in normal (O) and Wilson's disease (●).

determined serially in 0.2 ml. of portions of plasma by counting it in a  $\beta$ -liquid scintillation counter 10 days after the experiments in order to allow for the disappearance of copper-64 activity.

(4) *The state of copper-64 in the in vivo labelled erythrocytes.* In order to determine whether copper-64 in erythrocytes, labelled *in vivo*, could pass from the cells back into the plasma, serial blood samples (5 ml.) were taken from the experimental subjects at different times after the intravenous administration of copper-64. The erythrocytes were separated by centrifugation at 3,000 r.p.m. for 5 min at 5° C, and the plasma discarded. The cells were washed twice in 5 ml. of ice cold 0.9 per cent sodium chloride, recentrifuged and assayed for copper-64 activity.

3 ml. of normal human plasma was added to the washed red blood cells, and the reconstituted blood was incubated at 37° C for 6 h in the Dubnoff metabolic shaker in an atmosphere of 95 per cent oxygen-5 per cent carbon dioxide. After incubation, 1 ml. of plasma was separated and assayed for radioactivity.

The activity remaining in the erythrocytes after incubation for 6 h was also determined by counting directly the twice washed and centrifuged red blood cells by procedures already described.

The experimental results can be summarized as follows:

(1) *The in vivo uptake of copper-64 into erythrocytes of normal and Wilson's disease subjects (Fig. 1).* In the normal human (O---O), there is an initial rapid uptake of copper-64 into the RBCs in 5-10 min, after which there is a decline in the RBC activity. This decline is followed by a secondary rise in the red blood cell copper-64 activity in 1 h, which is slower than the initial rise, and reaches a near maximum in 18-20 h.

The erythrocytes of the patient with Wilson's disease (●---●) differ from this pattern. Initially, there appears to be significantly greater uptake, followed by a precipitous decline in RBC copper-64 content. This is followed by fluctuations in the activity of red blood cells, which continue for several hours and only after a delay of 10-12 h is there a secondary rise in erythrocyte copper-64 activity, which is, however, much lower than in the normal subject.

The total red blood cell content on two consecutive days was found to be no different in the normal subject and in his diseased sibling, that is, 60, 69  $\mu$ g per cent and 69, 67  $\mu$ g per cent, respectively.

(2) *The effect of amino-acids on the transfer of copper-64 across a semi-permeable membrane.* This was investigated using a purified albumin solution (O---O), normal fresh human serum ( $\Delta$ --- $\Delta$ ), and the serum of the patient with Wilson's disease (x---x) as basic media. The results are shown in Fig. 2.

When a 4 g per cent solution of albumin in Krebs-Ringer-bicarbonate buffer at pH 7.4 with added copper-64 was dialysed through a semi-permeable membrane against the same albumin solution with no added copper, almost

no transfer occurred in 24 h (O---O). The addition of the twenty naturally occurring amino-acids in physiological concentration resulted in a 40 per cent transfer of copper-64 during the same period (●---●). When normal human serum was dialysed before an identical experiment in order to remove most of the amino-acids, it behaved in exactly the same way as purified albumin ( $\Delta$ --- $\Delta$ ), while native serum, with all its amino-acids present, also resulted in a 40 per cent transfer in 24 h ( $\Delta$ --- $\Delta$ ). Serum from the patient with Wilson's disease (x---x) gave similar results.

The results suggest that amino-acids are important in making albumin-bound copper diffusible, and that this action on the transfer of copper-64 across a 'Cellophane' membrane is similar *in vitro*, whether purified human albumin solution, normal human serum or serum of a patient with Wilson's disease is used.

(3) *The transport of copper-64 into erythrocytes as facilitated by amino-acids in vitro (Fig. 3).* The presence of the naturally occurring amino-acids in serum results in a significantly greater uptake of copper-64 into red blood cells (●---●), compared with the same serum after dialysis and removal of most of the amino-acids (O---O).

When 4  $\mu$ molar L-histidine ( $\blacklozenge$ --- $\blacklozenge$ ) is added to medium free from amino-acid, greater uptake of copper-64 results than in the control experiments. There is an initial rapid uptake of copper-64 during the first 5 min, followed by a decline in RBC copper-64 content. This

Fig. 2. The effect of amino-acids on the *in vitro* transfer of copper-64 across a semi-permeable membrane. (Copper/albumin molar ratio 2:1, pH 7.4, 37° C.) O, Albumin (human); ●, albumin + 20 amino-acids;  $\Delta$ , human serum;  $\Delta$ , dialysed human serum; x, Wilson's disease serum.

Fig. 3. The effect of amino-acids on the uptake of copper-64 by erythrocytes *in vitro*. (95 per cent oxygen-5 per cent carbon dioxide, pH 7.4, 37° C.) O, Dialysed serum (no amino-acids); ●, native serum (all amino-acids); ◆, dialysed serum + histidine.

rapid initial uptake and decline of copper-64 is followed by a slower rate of uptake of the isotope over the period of the experiment.

These results suggest that amino-acids enhance the uptake of copper by normal erythrocytes *in vitro*.

The ratio of the activity in 1 ml. of packed red blood cells to the activity of 1 ml. of plasma is less than unity. A ratio less than one suggests diffusion<sup>20</sup>, and it appears that histidine and other amino-acids enhance the uptake of copper-64 into red blood cells by making the albumin-bound copper diffusible and that the mode of entry of copper into RBCs is apparently by diffusion. In experiments in which a double label technique was used with <sup>14</sup>C-L-histidine and copper-64, both in 4  $\mu$ molar concentrations (Fig. 4), however, facilitated diffusion is suggested.

The changes in the level of labelled histidine (●—●) in plasma were determined in relation to the uptake of copper-64 (○—○) into the red blood cells (Fig. 4). Initially, there is a rapid uptake of copper-64 into the red blood cells, and a disappearance of histidine carbon-14 activity from the medium. With the counterflux of copper from the RBCs after the initial uptake there is a corresponding increase in the concentration of carbon-14 histidine in the medium. The beginning of the secondary uptake of copper-64 by RBCs corresponds with the disappearance of <sup>14</sup>C-histidine from the medium. At 1 h the plasma <sup>14</sup>C-histidine level rises again, as if transport from then on reaches a steady equilibrium.

These results suggest that the uptake of copper-64 by RBCs is related to a lowering of the histidine concentration in the suspending medium, because copper and histidine are probably moving simultaneously from the plasma compartment into the erythrocyte fraction.

(4) *The state of diffusibility of copper-64 in the in vivo labelled erythrocytes at different intervals of time after the intravenous administration of copper-64 (Fig. 5).* In normal erythrocytes (○—○) the amount of dialysable copper-64 decreases sharply with time, and 35 h after the

Fig. 4. The *in vitro* relationship of plasma histidine carbon-14 concentration to uptake of radiocopper-64 by erythrocytes. (64  $\mu$ moles, H15-4  $\mu$ moles, pH, 7.4, 37° C). ●, H15 C-14 in plasma; ○, Cu-64 uptake by RBCs.

Fig. 5. Total diffusible copper-64 fraction of *in vivo* labelled erythrocytes in normal (○) and in Wilson's disease (●).

Fig. 6. Hypothetical metabolic pathways of red blood cell copper. Alb Cu, Albumin bound copper; AA, amino-acids; AACu, amino-acid-copper complex; FCu, erythrocyte copper.

injection of radiocopper-64, only 20–30 per cent of the initial activity remains in a labile, dialysable state.

In Wilson's disease (●—●), on the other hand, during the first 20 min after injection all the copper-64 in red blood cells is dialysable, and at 18 h 60 per cent of the erythrocyte copper-64 content can still be diffused. From then on, there appears to be a gradual decline in the total diffusible fraction, but it is still significantly greater than normal at 35 h.

The present studies suggest that amino-acids play a part in the uptake of copper into erythrocytes. Both the *in vivo* and *in vitro* experiments show that there is an initial rapid transport of copper-64 by the erythrocyte fraction in the first few minutes. This flux of copper-64 appears to be followed by a counter-flux of copper out of the cells. A similar phenomenon of transport and counter-transport has recently been reported by Winter and Christensen, who investigated the migration of amino-acids across the membrane of the human erythrocyte<sup>21</sup>.

The exact nature of the copper transport into erythrocytes as facilitated by amino-acids is not fully explained by our experiments. We cannot exclude the possibility that the initial hump is due to adsorption on the cell surface. The entry of copper by simple diffusion through a lipid barrier seems unlikely to account for the phenomenon of counter-transport. Further experiments are in progress to elucidate this problem.

The initial phenomenon of rapid transport and counter-transport of copper-64 is followed by a slower rate of uptake of copper-64 by erythrocytes. This can be demonstrated in both the *in vitro* and *in vivo* experiments. The rate of this secondary uptake of copper-64 is significantly lower than the initial rate of uptake, and reaches a near maximum in 24 h in the *in vivo* experiments.

This secondary uptake of copper-64 into erythrocytes corresponds with the formation of a non-dialysable, stable copper complex in erythrocytes. The rate limiting factor may be the rate of formation of this latter complex. This portion of erythrocyte copper-64 probably represents binding of the radiocopper-64 to a copper protein of RBCs: "erythrocyte copper-64" complex. Although there is no evidence that erythrocyte copper exists as an apoprotein, or one with only a partial complement of copper, this must be seriously considered, unless one postulates the existence of a new stable copper-protein complex.

The erythrocytes of the patient with Wilson's disease seem to differ from the normal, mainly in a quantitative manner. There is significantly greater initial uptake of copper-64 by his erythrocytes. This initial greater uptake cannot be explained by the difference of the serum albumin binding capacity of Wilson's disease, because we have shown (Fig. 2) that it behaves in exactly the same way in normal human serum. Nor is it due to increased serum amino-acid concentrations in Wilson's disease, because these are known to be normal<sup>19</sup>. It seems likely to be

related to the fact that the half-life of circulating albumin-bound copper-64 is usually longer in Wilson's disease. In these experiments it was found to be 13 min in the patient with Wilson's disease, compared with 8 min in the normal subject. In time, however, incorporation of copper-64 into the non-dialysable form will take place in HLD erythrocytes, indicating that the copper bound to "erythrocuprein" is in a slow dynamic equilibrium with the copper present in a labile form in red cells. A similar reduction in RBC stable copper was found in one of two patients with Wilson's disease studied by Shields<sup>24</sup>. This defect in copper-64 incorporation into the stable pool may have a parallel with the hepatic defect in ceruloplasmin formation.

Table 1. CHARACTERISTICS OF RED BLOOD CELL COPPER

Features	Labile pool	Stable pool
Chemical nature	Amino-acid bound	Protein bound ("Erythrocuprein")
Affinity for copper	? Non-specific	Specific
Copper turnover	Fast	Slow
Nature of transport	Bidirectional	Primarily unidirectional
Origin	Diffusion (? facilitated)	Unknown
	Extracellular fluid (plasma)	Intracellular fluid (RBC)
Distribution of copper-64 35 h after intravenous injection		
Normal RBC	20-30 per cent	70-80 per cent
Wilson's disease RBC	50-60 per cent	40-50 per cent

The experiments reported in this article confirm the previous findings of two copper pools in erythrocytes in both normal and Wilson's disease subjects (Table 1).

(1) A dialysable compartment, in which the movement of copper is fast and bidirectional. The chemical nature of this pool is probably copper bound to amino-acids. Its copper originates from the albumin bound copper of plasma, which is made more freely diffusible through cell membranes by amino-acids. This pool has been called the "labile" pool by Bush<sup>6</sup>.

(2) A non-dialysable copper pool which binds copper strongly, and its copper turnover is slow and primarily unidirectional. The chemical nature of this pool is likely copper bound to erythrocuprein, a protein of molecular weight 33,400, which binds two atoms of copper per molecule of protein<sup>23</sup>. In the normal erythrocyte, when this pool is labelled *in vivo*, only 20-30 per cent of the total red blood cell copper-64 is found in this compartment. The exact nature of the transport across erythrocyte membranes has not yet been completely elucidated, but it is likely to be facilitated diffusion. The nature of the transport of copper from the amino-acid pool into the stable pool is unknown. The formation of this stable copper pool in Wilson's disease is much delayed, but we have no evidence at present which indicates that this

may be primary or secondary. The diagrammatic representation of the hypothetical metabolic pathways of red blood cell copper is shown in Fig. 6.

In conclusion, we have studied the uptake and kinetics of radiocopper-64 by human erythrocytes in normal people and in a patient with Wilson's disease *in vivo* and *in vitro*. Amino-acids increase the rate of uptake of copper-64 by erythrocytes, probably by facilitated diffusion. The chemical nature of the "labile" pool in erythrocytes appears to be diffusible copper bound to amino-acid. A phenomenon of transport and counter-transport is described for copper in the human erythrocyte.

Apparent kinetic differences have been observed between the erythrocytes of two normal people and one patient with untreated Wilson's disease. An initial greater uptake and a marked delay in incorporation of copper-64 into the non-diffusible pool were noted. More cases will have to be studied to verify and elaborate on these findings.

We thank Mrs. Mary E. Baudin and Miss Roberta L. Rasmussen for their technical assistance, and Dr. Eleanor R. Harpur for her helpful suggestions. This work was supported by the Medical Research Council of Canada and the Montreal Children's Hospital Research Fund.

## Cortisol in the Regulation of RNA and Protein Synthesis

by  
CHEV KIDSON\*

Baker Medical Research Institute,  
Melbourne, Australia

The initial events involved in the regulation of RNA and protein synthesis by the hormone cortisol are rapid. This suggests that steroid hormones act as effector molecules in induction and repression.

HORMONE control of gene expression is clearly demonstrated by morphological evidence which is receiving increasing support from biochemical data (reviewed by Davidson<sup>1</sup>). Interest in the molecular basis by which hormones operate gene functions centres particularly on the way in which they can achieve selectivity of action, causing the induction of some cistrons and the repression of others in the same genome<sup>2</sup>. These selective effects,

which possibly include competitive, antagonistic actions of two or more hormones on the synthesis of a single gene product<sup>3</sup>, may collectively represent a system of hormonal programming of gene expression<sup>4</sup>.

Talwar *et al.*<sup>5</sup> have reported evidence that oestradiol-induced derepression of RNA synthesis in rat uterus is mediated through an oestradiol-binding protein. T'so and Lu<sup>6</sup> observed binding of testosterone to DNA, a finding which could suggest a direct action of the hormone on transcription, but others<sup>7</sup> have failed to obtain evidence

\* Present address: Department of Molecular Genetics, Institute of Hormone Biology, Syntex Research Center, Palo Alto, California.

Fig. 1. Rapid effect of cortisol on the synthesis of rapidly labelled RNA in rabbit lymph node cells. Cortisol (5  $\mu$ g/ml.) was added at varying times before a standard 2 min pulse of  $^3$ H-uridine (10  $\mu$ c./ml.). 5 ml. incubation volume.

for DNA-binding of cortisol. Certain data based on actinomycin-inhibition of the induced synthesis of enzymes by hormones suggest that the hormone effect involves the induced synthesis of the RNA template<sup>8</sup>, while other evidence from actinomycin experiments suggests that in some cases a hormone may control translation of the RNA template into enzyme protein<sup>9</sup>.

At the present time it is not possible to visualize a single functional model which will account for the control of RNA and protein synthesis by steroid and peptide hormones, by different hormones in the same class, or even by a single hormone on different genetic loci. Many of the effects of cortisol, for example, have been studied over periods of several hours<sup>7</sup>, times which are long when considering the rapid events involved in the initiation of RNA and protein synthesis. Recently, however, it has been demonstrated that cortisol alters RNA synthesis in seconds or minutes<sup>10</sup>, times which are more in keeping with the expected kinetics of initial events in induction and repression. Before it is feasible to build even preliminary models of hormone action on gene expression it is essential to know whether altered transcriptional (RNA synthesis) or translational (protein synthesis) events occur first and to know whether these alterations may be dissociated in time. The present studies, which examine critically the kinetics of cortisol action on RNA and protein synthesis in short time periods in isolated lymphoid cells, suggest that these events can be dissociated to some extent and that the initial effects are directed at the level of transcription.

Suspensions of lymphoid cells were prepared from mesenteric lymph nodes of two or more rabbits<sup>10</sup> and incubated in Dulbecco medium<sup>11</sup> containing 1 per cent glucose. The cell suspension was divided into a number of aliquots to allow internal controls in each experiment. Cortisol, as hydrocortisone sodium succinate, was added in solution where indicated. RNA was pulse-labelled with  $^3$ H-uridine; protein was labelled with  $^3$ H- or  $^{14}$ C-leucine, or with  $^3$ H- or  $^{14}$ C-phenylalanine. RNA synthesis was expressed per mg DNA and newly synthesized RNA was isolated by a modified<sup>10</sup> two-stage phenol procedure<sup>12</sup>. In experiments measuring protein synthesis, incubation was ended by the addition of ice-cold, unlabelled leucine or phenylalanine (to give a dilution  $> 1/1,000$ ), followed by half a volume of 20 per cent trichloroacetic acid. The precipitate was washed with boiling trichloroacetic acid, cold trichloroacetic acid, ethanol and acetone. Radioactivity was assayed in a liquid scintillation counter; protein was first dissolved in tetraethylammonium hydroxide before adding the liquid phosphor.

In one group of experiments the effect of cortisol on RNA synthesis was assessed in spleen cells from rats adrenalectomized three to five days previously and maintained on saline, without exogenous steroids. Spleens were removed, cell suspensions prepared<sup>10</sup>, and RNA

synthesis measured after incubation in the presence or absence of cortisol.

Cortisol rapidly alters the synthesis of rapidly labelled RNA in lymphoid cells, as illustrated in Fig. 1. In this type of experiment cortisol was given for varying times before a 2 min pulse with  $^3$ H-uridine. Other experiments<sup>10</sup> which have examined the effect of a standard cortisol pulse and varying pulse-times of  $^3$ H-uridine suggest that the initial effect is probably initiated in seconds, becoming readily measurable in 1–2 min. Adrenalectomy accentuates this rapid effect of cortisol on RNA synthesis (Table 1). Basal RNA synthesis was greater in spleen cells from adrenalectomized rats than in cells from controls, and the proportional change in rate of labelling of RNA when incubated with cortisol was greater in cells from adrenalectomized than from control animals. It is evident that in both types of lymphoid tissues—rabbit lymph node cells and rat spleen cells—the net effect caused by cortisol is a decrease in RNA synthesis, as observed by Feigelson and Feigelson<sup>7</sup> during periods of several hours. The method of RNA preparation used excludes terminally labelled rRNA (ref. 10), but the rapidly labelled material may include RNA other than messenger RNA (refs. 10 and 13). The cortisol effect is selective in these tissues as it is in rat liver<sup>2</sup>.

Table 1. EFFECT OF SHORT PULSES OF CORTISOL ON INCORPORATION OF  $^3$ H-URIDINE (5 MIN PULSE) INTO RNA OF SPLEEN CELLS FROM INTACT AND ADRENALECTOMIZED RATS

Treatment	Intact rats (c.p.m./mg DNA)	Per cent decrease + cortisol	Adrenalectomized rats (c.p.m./mg DNA)	Per cent decrease + cortisol
Control (– cortisol)	5,315	–	9,950	–
+ Cortisol (1 min)	4,440	16	7,700	23
+ Cortisol (5 min)	3,540	33	4,900	51

The ultimate effect of cortisol on protein synthesis in lymphoid tissues is also a net decrease<sup>14</sup>. A kinetic analysis of short periods of time, however, indicates that a rather complex series of events precedes this general decrease. Fig. 2 shows the effect of a pulse of cortisol added to the cell culture at various times before a standard incubation of 20 min with radioactive leucine. The eventual decrease in rate of protein synthesis was preceded by a significant rise in the rate of leucine incorporation, which was maximal with a pre-leucine cortisol pulse of about 5 min. When the leucine incubation period was reduced to 5 min a delay was apparent in the appearance of this "burst" of increased protein synthesis (Fig. 3), suggesting that some time (10–15 min) is required before any effect of cortisol on protein synthesis becomes measurable.

Fig. 2. Effect of cortisol on protein synthesis in rabbit lymph node cells. Cortisol (5  $\mu$ g/ml.) was added at varying times before the addition of  $^3$ H-leucine (5  $\mu$ c./ml.) for 20 min. 2 ml. incubation volume. ■, Control; ●, cortisol.

This observation was verified in another way, by using a standard cortisol pulse (5 min) and varying leucine pulse-times (Fig. 4a). Increased  $^3\text{H}$ -leucine incorporation in the presence of cortisol was measurable only after 15–20 min. A similar result was obtained using  $^3\text{H}$ -phenylalanine (Fig. 4b). If earlier effects are exerted by cortisol on amino-acid incorporation into protein, they are not recognizable by these techniques. The present results do not exclude, of course, qualitative changes in protein synthesis which may be induced earlier by cortisol.

The times of both RNA and protein synthesis effects could be influenced by the rate of uptake of cortisol into the lymphoid cells, a possibility which was investigated by the use of radioactive cortisol. Cortisol-1,2- $^3\text{H}$  was converted to the succinate by incubation with succinic anhydride in the presence of pyridine, the pyridine then being removed under vacuum. The water-soluble  $^3\text{H}$ -cortisol succinate was added to cell suspensions which had been incubated at  $37^\circ\text{C}$  for varying times before they were poured into 20 volumes of ice-cold Dulbecco medium. The cells were washed three times with ice-cold medium to remove non-adsorbed cortisol, then the amount of cortisol taken up by the cells was measured by assaying radioactivity. Uptake of the steroid was linear during the first 2 min and reached a maximum after about 5 min (Fig. 5). Cortisol-induced decrease in the rate of RNA synthesis in lymphoid cells is also maximal after about 5 min<sup>10</sup>. The correspondence of these two times suggests that the extent of the measurable cortisol effects on RNA synthesis is limited by the time required to achieve maximal availability of intracellular steroid. This observation supports the conclusion from previous data<sup>10</sup> that cortisol exerts its effect on RNA synthesis extremely rapidly, probably within seconds of entry into the cell.

The sequence of events which follow the uptake of cortisol into the lymphoid cells thus appears to be: (1) a net decrease in the rate of synthesis of rapidly labelled RNA, occurring in seconds; (2) an initial lag of several minutes before there is any effect on protein synthesis; (3) a "burst" of increased protein synthesis, maximal after 15–20 min; (4) a final net decrease in the rate of protein synthesis. The inference is that transcriptional (RNA synthesis) effects caused by cortisol precede translational (protein synthesis) effects. The transcriptional effects could be induced by direct binding of the steroid to DNA (ref. 6) (but this is unlikely in view of negative evidence for cortisol-DNA association<sup>7</sup>) via protein-bound hormone<sup>8</sup> or even by direct binding of the steroid to RNA. The kinetics indicate, however, that any binding which is operative in the initial stages of cortisol action on RNA synthesis must be between the steroid and pre-existing macromolecules.

A decrease in messenger RNA synthesis would be expected to result in decreased synthesis of the corre-

Fig. 3. Effect of cortisol at an earlier stage of protein synthesis in rabbit lymph node cells. Cortisol ( $5\text{ }\mu\text{g/ml}$ ) was added at varying times before the addition of  $^3\text{H}$ -leucine ( $5\text{ }\mu\text{C/ml}$ ) for 5 min. 2 ml. incubation volume. ■, Control; ●, cortisol.

Fig. 4. Effect of cortisol on the incorporation of leucine and phenylalanine into protein in rabbit lymph node cells. A standard 5 min pulse of cortisol ( $5\text{ }\mu\text{g/ml}$ ) was followed by the addition of (a)  $^3\text{H}$ -leucine ( $5\text{ }\mu\text{C/ml}$ ) or (b)  $^3\text{H}$ -phenylalanine ( $5\text{ }\mu\text{C/ml}$ ) for varying time periods. 2 ml. incubation volume.

Fig. 5. Uptake of  $^3\text{H}$ -cortisol by rabbit lymph node cells.  $^3\text{H}$ -cortisol ( $5\text{ }\mu\text{C/ml}$ ) was added to 2 ml. volumes of cell culture at zero time, then the culture was poured into 20 volumes of ice-cold medium at varying times to dilute radioactivity and limit further absorption.

sponding proteins, following a lag related in length to messenger stability. The occurrence of an intervening "burst" of increased protein synthesis, however, indicates that a more complex situation exists. The most probable explanation is that the rapidly labelled RNA is comprised of heterogeneous species, and that in addition to messenger RNA and ribosomal RNA precursors, some of this RNA subserves regulatory functions. Assuming that many messenger RNAs are fairly stable<sup>15</sup>, a simple model will explain the present data (Fig. 6). Such a model does not distinguish between direct repressor function of some rapidly labelled RNAs and repressor proteins synthesized on these RNAs as templates. What it does indicate is that repressor RNAs or repressor template RNAs would require to be less stable than the messenger RNAs (coding structural or enzyme proteins) the function of which they regulate. Considered from the point of view of induction or repression of a structural (enzyme) protein, the hormone would actually appear to act at the level of translation rather than transcription<sup>3,9</sup>.

Alternatively, it is possible that some of the "burst" proteins are regulatory in function (Fig. 7). In this model, the binding of cortisol to repressor proteins would lead both to the repression of messenger RNA synthesis and to the increased "burst" synthesis of more repressor proteins. This would imply that repressors regulated their own synthesis; it would also imply that synthesis of such repressors is inducible, an observation which so far seems unlikely in bacteria<sup>16</sup>.

It will not be possible to decide between models of this type or others until more knowledge is available on the nature of macromolecular binding of cortisol relevant to its gene regulatory functions. To account for the observed selectivity of action<sup>2</sup> of cortisol in a given tissue and the differing responses of liver and lymphoid tissues to cortisol<sup>7,10</sup>, the hormone must be able to cause both induction and repression of different regions of the same genome, a possibility which, on theoretical grounds, is most likely to result from the versatility of hormone-protein complexes<sup>17</sup>. What the present data show is that the initial events involved in cortisol regulation of RNA and protein synthesis are extremely rapid, a finding which favours a

Fig. 7. Alternative model of cortisol regulation of lymphoid RNA and protein synthesis.

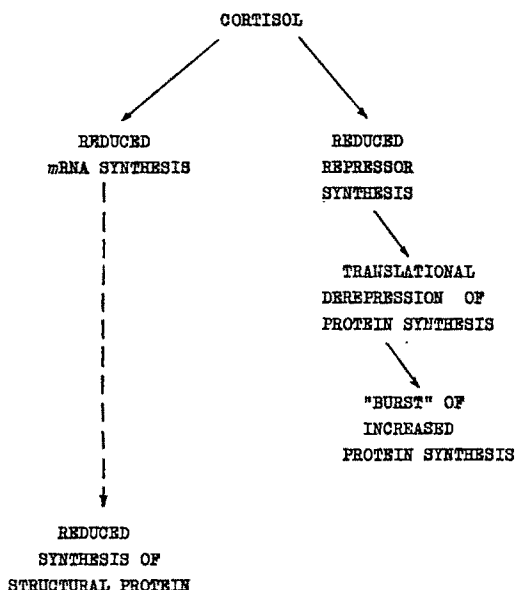

Fig. 6. Model of possible sequence of events in the regulation by cortisol of lymphoid RNA and protein synthesis.

direct role of the steroid hormone as an effector molecule in induction and repression.

## Sorption and Swelling within Wood Cell Walls

by  
G. N. CHRISTENSEN

CSIRO Division of Forest Products, Melbourne,  
Australia

Rates of swelling of wood cell walls in water and alcohol suggest that the mechanism of uptake of liquid and vapour involves two stages—wetting or adsorption at capillary surfaces followed by molecular penetration and swelling of the solid phase.

MANY years of research have not completely revealed the mechanism by which water enters or leaves the wood cell wall in the course of the swelling or shrinkage of wood<sup>1</sup>. It has generally been assumed that the rate of change of moisture content is controlled by diffusion, and complicated by the intricate cell wall structure and probable occurrence within the cell wall, at least in its saturated state, of capillaries or continuous water pathways. I have shown, however, that so long as specimens are made sufficiently thin, the rates of sorption of water vapour in the absence of air by wood<sup>2</sup>, wood pulp<sup>3</sup>, hemicellulose<sup>4</sup> and regenerated cellulose film<sup>5</sup> are determined by a mechanism which differs markedly from diffusion in its

dependence on the conditions of sorption. As evidence for this conclusion, it was found that (a) below a limiting thickness, sorption rate was independent of material thickness; (b) for moisture increments of a given size, the sorption rate was markedly lower at higher initial moisture contents, whereas the diffusion coefficient is known to be greater at higher moisture contents; and (c) for the same final moisture content, large moisture increments were completed much faster than smaller ones.

Following Bagley and Long<sup>6</sup> and later workers, it was postulated that the rate of sorption by such thin materials was limited by relatively slow molecular re-arrangements

within the swelling substance. It was further suggested that the speed of this re-arrangement was dependent on swelling pressure or change in free energy, because the rate of sorption resulting from a change in relative vapour pressure from  $p_i$  to a final value of  $p_f$  was found to be related empirically to  $\log p_f/p_i$ , for values of  $p_i$  other than zero.

This work has now been extended to measurement of the rates of swelling of wood cell walls after rapid wetting with liquid. It soon became clear that the above mechanism alone could not account for the behaviour observed when liquid replaced vapour as the external phase, nor were the results any more consistent with diffusion as the rate-controlling mechanism than with sorption of vapour.

The experiments were conducted mainly on the wood of klinki pine (*Araucaria hunsteinii* K. Schum. syn. *A. klinkii* Lauterb.) with fibres about 7 mm long, and with walls 3–4  $\mu$  thick. The liquid, namely water, methanol or ethanol, was brought into intimate contact with all cell wall surfaces in a very short space of time, generally less than 0.2 sec and, in some cases, within 0.02 sec. This was achieved by using cross sections of wood approximately 2–3 mm in the fibre direction, that is, shorter than the fibre. Specimens were initially evacuated and either completely dried or conditioned to equilibrium at a selected vapour pressure in the absence of air. De-aerated liquid under atmospheric pressure was then rapidly admitted to the specimen and the course of transverse swelling of the specimen was recorded photographically at up to 8,000 exposures/min. It was assumed that the measured external swelling of the specimen reflected the behaviour of all its fibres swelling simultaneously.

Table 1. RATES OF SORPTION AND SWELLING CHARACTERIZED BY THE RECIPROCAL OF THE HALF-TIME\*

	Sorption of vapour		Swelling in liquid ( $p_f=1$ )		
	Water	Methanol	Water	Methanol	Ethanol
$p_i = 0$	$2 \times 10^{-4}$	$1 \times 10^{-3}$	1.5	$1 \times 10^{-1}$	$1.5 \times 10^{-2}$
$\frac{p_i}{p_f} = 0.7$	$6 \times 10^{-4}$	$1 \times 10^{-4}$	1	$1.5 \times 10^{-3}$	$2 \times 10^{-5}$
$\frac{p_i}{p_f} = 0.8$	$2.5 \times 10^{-4}$	$2.5 \times 10^{-5}$	$2 \times 10^{-1}$	$3 \times 10^{-4}$	$3 \times 10^{-6}$
$\frac{p_i}{p_f} = 0.9$	$3 \times 10^{-4}$	—	$5 \times 10^{-2}$	$2.5 \times 10^{-4}$	—

The measurements (in sec) were made on wood of klinki pine.

\* The "half-time" is the time taken to reach half the change in sorption or swelling occurring between the initial and final equilibrium conditions.

The main observations from these measurements of rate of swelling include the following. (Some of these observations are illustrated by the results in Table 1.) (a) The rates of swelling in liquid (water and methanol) were several orders of magnitude faster than the rates of sorption of the corresponding vapour. (b) Specimens conditioned first to alcohol vapour swelled more slowly on immersion in the corresponding liquid than specimens not conditioned. The swelling rate was strongly dependent on  $p_i$  in a manner closely parallel to the dependence of the vapour sorption rate on  $p_i/p_f$ . (c) Swelling in water showed a similar strong dependence on  $p_i$ , but only for values of  $p_i$  greater than about 0.7. For  $p_i$  of less than 0.7 the swelling rate was little different from that of dry wood. (d) At values of  $p_i$  below about 0.7, the swelling rate in water was strongly dependent on cell wall thickness, for example, ten times faster for samples of balsa (1  $\mu$ ) than for klinki pine (3–4  $\mu$ ) and faster for early wood than for late wood of radiata pine. At values of  $p_i$  above 0.7, that is, when the swelling rate in water was strongly dependent on  $p_i$ , differences caused by cell wall thickness were reduced or disappeared. (e) Swelling rates in methanol and ethanol were about three and five orders of magnitude lower respectively than the corresponding rates of swelling in water (for comparisons at  $p_i$  values of 0.7 or greater).

The following suggestions are now put forward as to a possible mechanism by which water or water vapour is taken up by wood cell walls. In arriving at this mechanism, several facts arising from both the vapour and liquid experiments seemed to be very important. These facts and their possible interpretations are as follows. (a) The uptake of liquid is much faster than that of vapour. This suggests that, in addition to the molecular processes of water transport and swelling within the solid phase, interfacial phenomena play a crucial part at some stage of the process. (b) Despite their difference in magnitude, the rates of uptake of both liquid and vapour are strongly and similarly dependent on the initial conditioning treatment. This suggests that basically similar mechanisms are involved in both liquid and vapour uptake, although modified by interfacial conditions. (c) Rates of uptake of both liquid and vapour are largely independent of material thickness under those conditions in which they are strongly sensitive to the ratio  $p_i/p_f$ . This suggests either that there are no significant gradients in time-dependent properties of the material (for example, concentration of sorbate) or that if gradients are present their boundaries lie at interfaces other than the geometric surface of the specimen. (d) The rate of uptake of liquid by wood initially dry or conditioned to a low vapour pressure was insensitive to previous conditioning but was strongly dependent on the thickness of the cell wall. It is possible that this behaviour results from a transition to a different controlling mechanism, analogous to that observed previously in vapour sorption by thicker wood samples<sup>7</sup>. As a result of that work, the mechanism controlling the vapour sorption rate at low initial vapour pressures was thought to be diffusion across a succession of wood fibres.

Elaboration of these ideas has led to the hypothesis that the uptake of both liquid and vapour involves two consecutive stages or processes. The first stage consists of the intrusion of either the liquid or vapour phase into the cell wall by a number of discrete pathways. It is possible that this consists of flow through pre-existing cell wall capillaries or void spaces in the dry or conditioned wood. For present purposes these need only be large enough to enable their contents, at the end of the first stage, to be regarded as a continuation of the liquid or vapour phase present outside the cell wall. At the same time, the spaces need only be frequent enough to divide the cell wall into regions which are small compared with its total thickness. The initial penetration and filling of capillaries is followed by the second stage—molecular migration into the intervening solid regions at a rate determined by the rate of molecular re-orientation or true swelling of the solid phase.

The first stage is strongly dependent on the thickness of the cell wall, that is the length of the capillary path, but not markedly so on initial conditions. The second stage, which occurs in a large number of regions of the cell wall simultaneously, is much less affected by cell wall thickness, but is markedly dependent on the initial vapour pressure conditions and also on whether it is vapour or liquid which is introduced at the interface.

The resultant rate of uptake is determined mainly by whichever of the two stages is slower in any given conditions. In cases where the molecular re-arrangement or true swelling can take place more rapidly (see below), the resultant rate of uptake is determined by the speed with which the external phase can penetrate the capillary structure during the first stage. This occurs when a critical thickness of the material is exceeded for any given set of otherwise constant experimental conditions. In vapour sorption, as stated above, this situation has been shown, for water vapour only, to be reached when the wood specimens are thick enough to require the penetration of a considerable number of fibres in succession. In immersion experiments, on the other hand, the critical thickness can be exceeded by a single cell wall. This occurs for the

uptake of water by klinki pine for all  $p_i$  values up to approximately 0.7.

With regard to the present series of investigations on small specimens, however, this constitutes exceptional behaviour. Thus, for immersion in water after conditioning to large  $p_i$  values, in alcohols for all  $p_i$  values, and for all vapour sorption experiments involving only single cell walls, the second or molecular swelling process is so slow relative to the first stage that it becomes rate controlling.

It now remains to explain why the rate of the second, or swelling, stage is dependent in the observed manner on both the initial conditioning treatment and the nature of the external phase. Together with the rapid filling of the capillaries with vapour or liquid, there will take place, at the capillary surfaces, adsorption of vapour in one case and surface wetting by liquid in the other. The change in surface properties of the solid at the capillary interface or, alternatively, the incorporation of sorbate within the first molecular layers which constitute the solid surface, leads to the development of a stress between the surface layer and the underlying unswollen material. The magnitude of this stress will depend on the steepness of concentration gradient of sorbate from the interface to the interior of the solid region. In the present context there are two factors which can affect this gradient. Other things being equal, it will be steeper the larger the difference between  $p_i$  and  $p_r$ , but the concentration gradient can also be expected to be larger the faster the quasi-equilibrium condition is established at the interface. It is reasonable to expect this to be much more rapid after wetting than after exposure to vapour.

So far the mechanism proposed for the swelling stage is indistinguishable from diffusion in which the surface concentration is time-dependent and stresses are present within the solid phase. That the controlling mechanism is not diffusion, even after immersion in liquid, is evidenced by, for example, the inordinately long times (up to several days or even weeks) required by the wet cell wall to reach swelling equilibrium when it starts from high initial sorbate contents. It is assumed that the rate of molecular

re-arrangement of the solid phase is the controlling mechanism and that this limits the rate at which additional sorbate molecules can enter the swelling structure. The other key assumption is that the rate of molecular re-arrangement at any point in the solid is determined by the magnitude of the stress produced at that point by the concentration gradient. The magnitude of this stress is related to events occurring initially at the solid surface, and so the complete course of swelling of each of the inter-capillary regions, that is the propagation of the concentration and stress gradients through it, is also determined by the events occurring at the surface. In this way, it is possible to explain the dependence of the measured rates of sorption and swelling on both the change in sorbate concentration, that is, on the values of  $p_i$  and  $p_r$ , and on whether liquid or vapour is used.

A further point of explanation which is necessary concerns the transport of sorbate molecules through the solid during the second or swelling stage. It is presumed that this occurs by a normal process of molecular diffusion, and that it takes place quite independently of the swelling. This is to say that diffusive transport of the additional sorbate, from the interface over the very short distance to any region in the solid where an increment in volume (swelling) is occurring, is potentially capable of proceeding many times faster than is actually required. The diffusion coefficient which should be used to characterize this potential transport rate should be that pertaining to steady-state (non-swelling) conditions. It follows that, in some circumstances, diffusion coefficients determined from non-steady state experiments, on sorbents which swell, may in reality be a measure of the swelling process rather than diffusion.

## Niche and Species Diversity in Neotropical Bats

by

J. R. TAMSITT

Department of Medical Zoology,  
School of Medicine,  
San Juan, Puerto Rico

In stable environments there seems to be some overlap of niches occupied by the Chiroptera.

A PERUSAL of the numerous faunal reports in the literature reveals that tropical environments support more species in a unit area than those of temperate zones. This situation has often been explained by the number of "niches" the habitat provides<sup>1</sup>. Until recently, explanations for the presence of a large number of species in an environment have either been unsatisfactory or vague, but an explanation of this phenomenon in terms of individuals of bird species has been dealt with theoretically and quantitatively. Klopfer and MacArthur<sup>2</sup> suggested and Schoener<sup>3</sup> elaborated that the principal factor which causes an increase in the number of birds in the tropics is an increase in similarity of the requirements of coexisting

species, and, as a consequence, an increased degree of niche overlap, that is, less exclusive requirements.

Similar sympatric species may diverge morphologically and show character differences, that is, two closely related species are often morphologically and ecologically most similar when in allopatry, and most dissimilar when in sympatry<sup>4</sup>. Hutchinson<sup>5</sup> demonstrated the measure of how dissimilar are coexisting bird species with similar habitats by observing that such species usually differ in the size of their feeding parts by a factor of 1.2–1.4. Bill length was used to determine ratios of character difference in coexistent tropical bird species of different body size<sup>2,6</sup>. Their extreme mean ratio values of 1.19–1.28 were less

than those found by Hutchinson, and differences in feeding parts were considered to be reduced between most sympatric tropical species, that is, the fewer the differences between species in feeding requirements, the closer to unity is the ratio.

The degree of character difference in a group of tropical phyllostomid bats was as much reduced as in tropical birds. Table 1 shows results which utilize congeneric pairs of bat species netted together in banana groves in Colombia, South America. The appropriate characters used to represent the feeding apparatus were the mandible and the upper tooth row ( $M^3$  or  $M^{2-3}$ ) as an upper jaw approximation. Mean ratio values of larger to smaller species were 1.15 and 1.14 for mandibular and tooth row measurements. MacArthur<sup>6</sup> postulated that the more similar are the food habits, the lower is the ratio. Simpson<sup>7</sup> questioned this postulate, but in only one bat species pair was there divergence in feeding habits. The ratio was high in bats of the genus *Phyllostomus* because of the larger size and highly carnivorous habits of the species *P. hastatus* (Table 1). Schoener<sup>8</sup> suggested that in birds the larger ratios ( $> 1.14$ ) occur when body sizes are large in proportion to the total abundance of food, smaller ratios resulting when species feed on more abundant foods in proportion to their body size. This relation, however, has yet to be established among bat species.

Table 1. CHARACTER DIFFERENCE AMONG MALES OF COEXISTENT BAT SPECIES OF COLOMBIA\*

Species	Mean mandible length	Ratio of large to small	Mean maxillary tooth row lengths	Ratio of large to small	Mean forearm length
<i>Myronycteris megalotis</i>	11.98	1.12	6.95	1.06	30.68
<i>M. nicefori</i>	13.45		7.40		38.55
<i>Phyllostomus discolor</i>	20.24	1.32	9.74	1.41	62.75
<i>P. hastatus</i>	26.73		13.70		86.94
<i>Glossophaga longirostris</i>	15.70	1.15	8.00	1.16	38.15
<i>G. soricina</i>	13.65		6.91		34.30
<i>Anoura caudifer</i>	15.79	1.11	8.03	1.14	35.23
<i>A. geoffroyi</i>	17.53		9.12		43.60
<i>Sturnira lilium</i>	15.83	1.07	6.85	1.10	41.67
<i>S. ludovici</i>	14.80		6.25		42.13
<i>Artibeus jamaicensis</i>	19.40	1.12	9.65	1.13	59.24
<i>A. lituratus</i>	21.64		10.94		67.08

\* Unpublished data.

Data presented here for bats correlate well with data for birds<sup>2,3</sup> and indicate that multiple occupation of niches or niche reduction may be characteristic of coexistent species in regions of high climatic stability where a constant food supply and abundance of roosting or nesting sites are available. The data suggest that habitat coexistent bat species of comparable sizes may have similar ecological requirements, but they do not explain why different sized bat species may also have similar ecological requirements (see forearm measurements, Table 1).

The spectrum of bat species netted in a habitat may be predicted within a relatively small margin of error, but observed populations appear to be controlled by local and temporal processes; simultaneous netting in two similar, adjacent habitats invariably results in some difference in numbers of individuals and species captured. Other than by casual observations, population dynamics of tropical bats have not been investigated, nor have the differences in composition of tropical bat communities been explained. The total probable bat biomass predicted was found to be essentially the same in two different tropical habitats<sup>6</sup>, one in which more kinds of food of similar form and palatability were present than in the other, although the communities observed were significantly different in composition, that is, in one habitat larger numbers of fewer species predominated, whereas fewer numbers of more species were present in the other. Reduction in competition by food partitioning<sup>3</sup> could be

a valid interpretation if this situation is found to be general in neotropical bats.

Coexistence of birds can obtain because each species occupying a habitat can be limited by the availability of a resource (food) in different habitats<sup>9</sup>. This relation has a direct bearing on bat community composition, and Pirlot<sup>9</sup> has asked: Do net captures of bats give an indication of resident populations or of communities coming to feed from other localities? To answer this, the diurnal roosting site of each species would have to be found and marking-recapture or telemetric investigation carried out, but probably in some habitats residential and feeding areas coincide, whereas in others the residential zone (with radius  $R$ ) contains within it one or more patches of feeding area of radius  $r < R$  (ref. 8). Where there are species in high numbers in a region, the residential and feeding areas are bound to overlap and to coincide occasionally (because bats, by the nature of their food source, are opportunistic).

Competition for food is possible in situations where many species in high numbers occur in a feeding area<sup>8</sup>, and actual food eaten indicates that coexistent bat species have certain common foods. Tropical bats constantly contend with "patchy" food sources, that is, scattered foods alternating in availability<sup>10</sup>, and consequently these bats do not specialize to feed on one or the other and are susceptible to irregular activities. These activities, however, are "convex", as the word is used by MacArthur and MacArthur<sup>7,9</sup>—the species is adapted to a scale of intermediate activities between the extremes of adaptive specialization (to a single food and to all palatable foods). Most neotropical phyllostomid bats (more than 51 per cent of the bat species in regions of high climatic stability in South America eat fruit or visit flowers to suck nectar and are only incidentally insectivorous or carnivorous) are convex in their activities, because many rather than a few foods are variably utilized<sup>11,12</sup>. (The usual classification of food habits is difficult to apply to bats because of their wide adaptation to different animal and plant foods. For example, many species which visit flowers in search of food in the tropics also eat fruit; some which visit flowers and eat fruit also use insects as a source of food and are omnivores.) Feeding sites, on the other hand, may or may not be convex, depending on the time of year (a habitat through which a bat could fly and in which it could feed would be convex). The number of bat species in a habitat, therefore, would be determined considerably by the convexity of the habitat. Unlike birds, the species diversity of which appears to be controlled largely by the structural diversity of the habitat<sup>10</sup>, the diversity and density of bats in a given habitat are controlled primarily by the amount of food (the number of convex habitats in the residential zone) and the number of available roosting sites. (Habitat structural diversity, for example, feeding in the canopy versus feeding at ground level, probably plays an important but unknown part in determining the diversity of bat species; capture by nets gives a biased sample, chiefly of fruit and nectar feeders flying near the ground.)

The roosting site factor is probably more important than the food factor to explain differences in composition of different communities of bats. If roosting sites are available, then the species will forage in a given residential zone. Conversely, even if food is present in the zone, the species may be absent because of a lack of roosting sites<sup>8</sup>. A considerable modifying factor of community components would be numbers of solitary species, for which roosting sites are abundant, and numbers of gregarious species, for which roosting sites are relatively less abundant. Tropical bats do not delimit territories, and the majority have a broad tolerance to a variety of roosting sites, nor is a nursery roost required for most, because the young can be carried with the female parent on foraging flights. These interactions of density dependent factors further contribute to the reduction in niche

restrictions and may explain considerably the flexibility in adaptations of bats in tropical regions.

## Growth Curves in Inbred Mice

by

ANNA KANE LAIRD

Argonne National Laboratory, Argonne, Illinois

ALMA HOWARD

Christie Hospital and Holt Radium Institute,  
Manchester

The application of a mathematical model to the growth of inbred mice and their  $F_1$  hybrids makes it possible to analyse the inheritance of growth.

STUDIES of gene effects on postnatal growth have usually depended on either quantitative comparisons of body-weight at a specified time after birth, or qualitative comparisons of the plotted growth curves. Use of these methods has permitted the identification of certain genetic influences on growth, such as the gene pygmy, *pg*, in mice<sup>1</sup> and the dwarfing mutation induced by methylcholanthrene<sup>2</sup>.

Crary and Sawin<sup>3</sup> used a fundamentally different approach to the study of the inheritance of growth and body size in rabbits, based on comparison of the absolute growth rates at significant times during growth. The absolute growth rate increases rapidly after weaning to reach a rather sharp maximum, and it then falls, at a slower and decreasing rate, to approach zero as an asymptote. Crary and Sawin found that when they classified rabbits on the basis of the magnitude and age of the maximum growth rate, and the age of reaching maturity, four hereditary classes of animals could be distinguished. They also identified a single gene as responsible for a sex difference in growth among dwarf animals.

This article outlines a new method of analysis of the inheritance of growth, based on the observation that the specific growth rate tends to undergo an exponential decay with increasing age<sup>4</sup>. When this observation is formalized in a simple growth model, a form of the Gompertz equation, the observed growth of an organism can be analysed by deriving the least squares fit of this equation to a set of growth data by means of a computer<sup>5-7</sup>. Three parameters are solved for: one is the specific growth rate at the start of the period of observation, the second measures the rate of exponential decay of the specific growth rate, and the third is the computed initial size of the animal. The mathematical nature of the growth equation is such that these parameters specify, for the theoretical curve, the asymptotic size approached at maturity, the age and the magnitude of the maximum daily growth rate, and the weight of the animal at any time selected for study by the observer. These quantitative characteristics of growth can be solved for by simple algebraic manipulation of the growth equation, and it is evident that they include the characteristics of growth used in previous studies of the inheritance of growth, and particularly those shown

by Crary and Sawin<sup>3</sup> to be of practical significance in defining hereditary differences among rabbits.

The data described here were collected between 1938 and 1945 in the Department of Genetics, McGill University. Stocks were derived from animals supplied by the Roscoe B. Jackson Laboratory or by L. C. Strong, and continued by brother-sister mating. The mice were housed, fed and managed throughout the period of observations under conditions which were made as uniform as possible. To reduce variation arising from the effects of litter size on postnatal growth, only four young of each litter were kept. They were chosen to represent the heaviest and lightest of each sex. A study of the sex-ratio at birth in strains A, dba, C<sub>57</sub>Black and I, and their hybrids, has been published<sup>8</sup>.

Young mice of eight inbred lines\* were weighed at birth and weekly thereafter for 10 weeks. Four of the lines (A, dba, C<sub>57</sub>Black and I) were chosen for further investigation. They were crossed in all combinations including reciprocals, and samples of the twelve types of hybrid animals were weighed as before. At the same time, fresh samples of young of the parent lines were weighed. The succession of weekly mean weights for each sex of each line constituted the growth data to which the curve described here was fitted. The number of animals of each sex weighed at each interval varied from 37 to 82 for the hybrids and their parental inbred strains; for the other inbred strains the number varied from 20 to 39, with the exception of the Jk strain, for which between ten and twenty animals of each sex were weighed.

For the mathematical analysis of the growth data, we used a Gompertz equation of the form

$$W = W_0 \exp \left( \frac{A_0}{\alpha} (1 - \exp(-\alpha t)) \right)$$

where  $W$  is the weight at time  $t$ ,  $W_0$  is the initial weight for the period of study, and  $A_0$  and  $\alpha$  are constants<sup>5</sup>.  $A_0$  is the initial specific growth rate, and  $\alpha$  measures the rate of exponential decay of  $A_0$ . Only the growth measure-

\* The standard nomenclature for the strains described in this paper is now: A, DBA, I, C57BL, C3H, JK, C57L, CBA. At the time the data were collected, the nomenclature had not been standardized.

ments from the second to the tenth weeks were fitted, because semi-log plots of the specific growth rate suggest that the rate of exponential decay characteristic of post-natal growth starts at about 14 days of age. Because  $t_0$  was set at 14 days, the values obtained for  $A_0$  and  $W_0$  are those characteristic of this age and are designated  $A_{14}$  and  $W_{14}$  in Tables 1-5.

The growth curve was fitted by a computer programmed to determine the Gompertz curve giving the least squares fit to the data, by an iterative fitting procedure. The standard errors on the parameters were derived using the coefficients from the inverted matrix<sup>9</sup>. Each point was weighted by the reciprocal of the variance. Points of biological interest on the growth curve, such as the asymptotic size approached by the early growth process studied here (see later), the age at which the inflexion point (the point of maximum absolute growth rate) was reached, and the instantaneous rate of growth at this time, were calculated using the transform equations derived in a previous study<sup>6</sup>.

The asymptote of this early growth process is not the size finally reached by the mice. As the Gompertz growth process slows at approaching maturity, a second, linear process becomes evident in mice and many other species (to be published). This linear process has relatively little effect on the early part of the growth curve studied here.

Fig. 1. Theoretical Gompertz growth curve fitted to the mean weights of  $C_{57}$  Black female mice by the method of least squares. The vertical bars are two standard errors of the mean.

Fig. 1 illustrates the theoretical Gompertz growth curve fitted to the mean weights of a representative set of animals. To the limited extent that one can judge by eye, it is evident that the fit is good. The mean deviation, without regard to sign, for these data was 2.5 per cent, and the deviations of the nine experimental points were, in order, 4.7, -7.1, 3.3, 5.2, -0.3, -1.5, 0.1, 0.5, and -0.2 per cent of the computed weights. The largest deviation for nearly all the sets of data occurred, as in Fig. 1, at the 21-day point, and it was always negative. For some of the curves the 28-day point was also below the curve. This characteristic tendency of the observed weights to lie below the curve at 21-28 days is almost certainly due to the minor malnutrition associated with weaning; it has been observed in other growth studies of

mice<sup>10</sup>. The effects of brief periods of malnutrition are known, however, to be only temporary, and afterwards growth takes place unusually fast until the animal has returned to its normal growth curve<sup>11</sup>.

In Tables 1 and 2 are given the parameters of the fitted growth curves, with their standard errors, for eight inbred strains of mice and for the twelve reciprocal crosses among four of them. The parameters differ only slightly from one another, and their standard errors overlap. Nevertheless, the biological significance of the small differences that do exist can be evaluated by the use of a sorting procedure based on sex, inbreeding versus hybridity, and the maternal and paternal strains.

Table 1. GROWTH CONSTANTS FOR INBRED STRAINS

Strain	$A_{14}$ *	$\alpha$ *	$W_{14}$ *

\* Table headings as for Table 1.

In Table 3 are summarized the results of sorting the animals by sex. With the single exception of  $W_{14}$ , the parameters of the growth curves and such other characteristics as the computed asymptote, and the age and magnitude of the maximum daily growth rate, all show a statistically highly significant tendency to differ in the two sexes. Because  $A_{14}$  is nearly always larger for the male and  $\alpha$  smaller, the ratio  $A_{14}/\alpha$  is larger for him, and the computed asymptote is higher (asymptote =  $W_{14} e^{A_{14}/\alpha}$ ). Furthermore, because  $\alpha$  is larger for the female,

Table 3. SEX DIFFERENCES IN GROWTH CONSTANTS

Growth constant*	Relation male to female	Incidence
$A_{14}$	Male greater	19/20
$\alpha$	Male less	17/20
$W_{14}$	Male less	10/20
Asymptote	Male greater	20/20
Max. growth rate	Male later	20/20
Age, max. growth rate	Male greater	19/20

\* Symbols for growth parameters as in Tables 1 and 2.

her growth curve is more compressed in time ( $\alpha$  is the inverse factor giving the relative duration of corresponding segments of the growth curve<sup>6</sup>). This means that she matures earlier, and reaches her maximum growth rate at a younger age than does the male; however, her maximum rate is less. The computed weight at 14 days shows no consistent difference between the sexes; this fact reflects the tendency of the growth curves to cross one another at about this time.

Table 4. RELATION OF GROWTH CONSTANTS TO HYBRIDITY

	Maternal strain	Paternal strain	Both parental strains
$A_{14}$ —male	12/12	11/12	11/12
female	11/12	10/12	9/12
$\alpha$ —male	12/12	11/12	11/12
female	12/12	12/12	12/12
$W_{14}$ —male	12/12	11/12	11/12
female	12/12	11/12	11/12
Maximum growth rate:			
Age, days—male	11/12	8/12	7/12*
female	11/12	10/12	10/12
g/day—male	12/12	12/12	12/12
female	12/12	12/12	12/12
Asymptote (g)			
Male	8/12	9/12	6/12
Female	11/12	10/12	9/12

\* Four of five exceptions are offspring of dba or I strain mothers.

The effects of hybridity on the properties of the growth curve are shown in Table 4. It is clear that with very few exceptions, the parameters for the hybrids are higher than those of the inbred mice of either parental strain. These differences have the effect that the hybrids reach their maximum growth rate about 1–6 days earlier, and the growth rate at this age is usually 25–60 per cent higher in the hybrids. The few exceptions are usually to be explained by the tendency of the offspring of dba or I mothers to have very low values for all the parameters

that affect it. In so doing, we have demonstrated differences in the growth curve and its parameters associated with sex, hybridity, and a maternal influence, in mice. Such effects have long been known in general terms, but the fitting of a growth equation and the determination of its parameters and mathematical properties permits the differences to be described with much greater precision than heretofore. Furthermore, the formalization of growth in an equation makes it possible to relate changes in the growth pattern to changes in the physiological determinants that are represented by the parameters of the growth equation. It is clear that a sigmoid curve of some sort is essential to describe the full growth curve of normal animals and their parts<sup>13</sup>. The Gompertz model has been shown to offer a satisfactory fit to the prenatal and postnatal growth of the guinea-pig over a 10,000-fold range<sup>5</sup>, a much more extensive range than is accounted for by another sigmoid curve, the logistic<sup>5</sup>. Regardless of the growth model used, however, species differences in the growth pattern must be genetically controlled. When animals as distantly related as cows, mice and chickens are compared with respect to their growth curves, it becomes evident that the growth patterns are superimposable<sup>14</sup>. Species differences are apparent only in the scale differences in the time and weight axes. Thus the hereditary process must act on the physiological parameters that are responsible for the dimensions of the scale. We have already shown in a study of the mathematical properties of the Gompertz growth equation<sup>5</sup> that the three parameters,  $W_0$ ,  $A_0$  and  $\alpha$ , are sufficient for complete specification of the two scales of the growth pattern. It is therefore reasonable to suggest that the three parameters may represent genetically determined, species-specific determinants of growth: the initial specific growth rate ( $A_0$ ), the rate of exponential decay of this growth rate ( $\alpha$ ), and the initial mass ( $W_0$ ). Within a species, these parameters can be modified slightly by

Table 5. MATERNAL EFFECT IN RECIPROCAL CROSSES

\* Headings as in Table 1. Exceptions in parentheses.

(see later). The differences in the computed asymptotes are generally quite small, and show no consistent effect of hybridity. A similar effect of hybridity on early growth rate rather than final size has been shown in chickens<sup>12</sup>.

Table 5 shows the regular differences observed in the parameters and properties of the growth curves of reciprocal crosses. To compare the respective crosses it is necessary to note from Tables 1 and 2 that the constants for the parental strains  $C_{57}Black$  and  $A$  are distinctly higher than for the strains  $dba$  and  $I$ , while within each of these pairs the values are closely similar. For  $A_{14}$  and  $\alpha$ , and for the age and magnitude of the maximum growth rate, there is no exception to the rule that the young of mothers from a strain characterized by high values for these constants will have higher values than the reciprocal hybrids. Thus the pattern of growth characteristic of the strain of the mother, whether early and fast or later and slower, is reproduced in the young. No consistent pattern was noted in the distribution of the values for the asymptote or for the computed weight at 14 days.

The principal purpose of this article has been to demonstrate the practical value of using a growth equation to analyse the pattern of the growth curve and the factors

such environmental factors as hormone status, nutrition, etc., as shown in the present investigation.

This work was supported by the U.S. Atomic Energy Commission. We thank M. H. Dipert and S. A. Tyler, of the Argonne National Laboratory, for the original fitting programme for the Gompertz equation, and A. D. Barton, of the same laboratory, for various additional programmes required in this investigation.

## Radio Diameter Measurements with Interferometer Baselines of One Million and Two Million Wavelengths

MEASUREMENTS of the angular sizes of radio sources made

with a 21 cm interferometer between Jodrell Bank and the Royal Radar Establishment, Malvern, over a baseline of more than half a million wavelengths have already been published<sup>1,2</sup>. Nine sources were shown to be smaller than 0.1 sec of arc in at least one dimension. During 1966 the performance of the digital fringe speed machine was greatly improved and, in addition to further measurements at 21 cm, observations were made at the shorter wavelengths of 11 cm and 6 cm, the radio telescope Mark II being used in place of the Mark I at Jodrell Bank. At the shortest wavelength the maximum effective baseline is greater than two million wavelengths.

*F*, indicates that fringes were observed. *NF*, indicates that fringes were not observed. —, indicates no observations.

\* Not observed at all hour angles, but shows no change in fringe amplitude between observations at substantially different resolutions.

§ All the identifications and red-shift measurements given here have been published, except those marked <sup>†</sup> which were kindly communicated to us by Professor Bolton in advance of publication. The red-shift parameter  $Z = \frac{\lambda - \lambda_{em}}{\lambda_{em}}$  where  $\lambda$  and  $\lambda_{em}$  are the wavelengths at which the radiation was observed and emitted respectively.

† The angular diameter,  $\theta$ , of each source is given for the shortest wavelength at which the source was observed.

The data at 11 cm were normalized and calibrated by means of frequent observations of the sources 3C 273B, 3C 279, 3C 286 and 3C 454.3. At the beginning of the observation period these sources were studied several times at all the hour angles at which they were more than  $10^\circ$  above the horizon. For these sources, as for sources at most declinations, the resolving power of the interferometer changes appreciably with hour angle as the sources move across the sky. The fringe amplitudes observed for the four normalizing sources did not change with hour angle and were approximately in the ratio of their flux densities. It was therefore concluded that all four of these sources were unresolved and so have sizes smaller than 0.05 sec of arc.

About fifty sources, for which there was evidence of small angular size and flux densities greater than 3 flux units at 11 cm, were next selected for study with this instrument. The evidence of small angular size came from previous interferometric work, from scintillation observations or from unusually flat radio spectra. These sources were observed in the first instance at times when the resolution was near minimum. Thirty-five of the sources selected showed significant fringe patterns. These sources were then observed for a second period at a time when the resolution was near maximum and the position angle of the radio source relative to the interferometer baseline was different. For most of these sources the fringe amplitudes in both cases were approximately those which would have been predicted from the published values of flux density at 11 cm combined with the calibration factors derived above.

Twelve of the sources were then studied in more detail by observing them continuously at all times when their elevation was greater than  $10^\circ$ . For eight of these sources no changes of fringe amplitude with hour angle were detected and it is concluded that they are also unresolved. The remaining four sources gave fringe patterns with a visibility significantly less than 1.0 at some or all hour angles.

Because so many of the sources observed at 11 cm appeared to be unresolved, it was decided to extend the observations to a wavelength of 6 cm, although the telescope efficiencies were lower at this short wavelength and the pointing errors likely to be more important. In ten days of observations fringes were observed from four sources, 3C 84, 3C 273B, 3C 279 and 3C 454.3, and these were studied at all the hour angles at which they were above  $10^\circ$  elevation. There is no evidence of any significant changes in their fringe amplitude. It is concluded that these sources, unresolved by a baseline of 2 million wavelengths, are smaller than 0.025 sec of arc. In the case of 3C 273B previous measurements<sup>1</sup> had suggested that the fringe amplitude changed with hour angle, but this change has since been traced to a tracking error<sup>2</sup>. Full analysis of all the data on 3C 273B, which includes additional measurements on 21 cm, leads to the conclusion that the source is unresolved at any of the wavelengths or baselines studied so far.

In addition to repeating the measurements of 3C 273B, several more sources were studied at 21 cm during 1966. All sources which gave fringe patterns in the combined programme are listed in Table 1, which also contains the results obtained in 1965. Of the forty-six sources listed, twenty-five have been identified with quasars and seven with radio galaxies. The remainder have not yet been optically identified, but it seems reasonable to predict that the majority are also quasars. Caution, however, should be exercised in attempting to make any statistical deductions because the sample of sources studied was not random.

It should be noted that the fringe amplitudes observed for the galaxies 3C 274 (Virgo A) and 3C 405 (Cygnus A) correspond to only a small fraction of the total flux density. 3C 274 appears to have an unresolved component which contains a few per cent of the total emitted flux at

both 21 cm and 11 cm. This component must have a linear dimension of less than 3 pc. A more detailed analysis of the results may show whether it is associated with the nucleus or with the jet of M87.

The fringes obtained at 21 cm from the sources 3C 343 and 3C 343.1 are of particular interest. Moffet<sup>3</sup> has shown that these sources, separated by 28.8 min of arc, are so remarkably similar that they are probably physically connected. Our measurements show that both of them are also among the sources that have angular dimensions of less than 0.1 sec of arc, corresponding to a ratio of separation to component size greater than 17,000 to 1. These dimensions are consistent with those deduced from the theory of synchrotron self-absorption<sup>4</sup>.

A number of sources are known to be variable at radio wavelengths, a characteristic generally considered to be associated with small dimensions. Table 1 shows that the ten radio variable sources listed by Pauliny-Toth and Kellermann<sup>5</sup> are all unresolved. These measurements have also permitted provisional interpretations of the radio structures of two quasars, 3C 138 and 3C 147, which both appear to have two separated components.

The interferometer observations described here demonstrate the remarkably high angular resolution that can be achieved at radio wavelengths. The results place new upper limits, by direct measurement, on the angular dimensions of the important class of radio sources characterized by small size and exceptionally high brightness temperature. Perhaps the most surprising result of the observations is the discovery that such a large number of sources have these small dimensions, and that this may be a general feature of most of the quasars. Any theory to account for these sources must explain the large radiating power being generated from such a small volume. For example, assuming the usual cosmological interpretation of their red-shifts, the upper limits to the linear dimensions of the quasar 3C 273B and the Seyfert galaxy 3C 84 are about 40 and 6 parsecs, respectively.

## Magnetic Fields in the Solar Corona

It has been proposed by Sturrock<sup>1</sup> that the frequency splitting sometimes observed in type II solar radio bursts may be caused by excitation of plasma oscillations by supra-thermal electrons moving through the solar corona in the presence of density irregularities and a weak magnetic field. He showed that in these circumstances

electromagnetic waves may be produced at two frequencies, one at the local plasma frequency  $f_p$  and one at frequency

$$f_2 = (f_p^2 + f_H^2)^{1/2} \simeq f_p + \frac{f_H^2}{2f_p}$$

where the local electron gyrofrequency  $f_H \ll f_p$ . He envisaged the possibility of using the observations to measure the magnetic field intensity, although the utility of type II frequency splitting as a technique for magnetic field measurements appears to be limited by its relatively infrequent occurrence. More recently, however, Ellis and McCulloch<sup>2</sup> have reported the observation of large numbers of a new type of solar bursts in which frequency splitting occurs regularly. These have been observed mainly between 20 Mc/s and 50 Mc/s, and usually appear as a pair of bursts separated in frequency by 100–200 c/s and lasting for about 2 sec.

It is of some interest, therefore, to examine whether these bursts have the properties expected from the theory of plasma radiation. These have been worked out in some detail by Tidman *et al.*<sup>3</sup>, who have found that for electrons with isotropic velocity distribution the observed wave intensity at  $f_p$  should be much less than at  $f_2$ , mainly through self absorption in the plasma near  $f_p$ . Where the radiation occupies a non-zero bandwidth centred on  $f_p$  and  $f_2$ , it might also be expected that the observed bandwidth near  $f_2$  would be greater than at  $f_p$ , again through self absorption for  $f < f_p$ . On the other hand, some non-isotropic electron velocity distributions lead to comparable radiation intensity at both frequencies, although still with different bandwidths.

A further property of bursts showing frequency splitting expected with the plasma radiation theory is that the frequency interval  $\Delta f = f_2 - f_p$  should increase with frequency. The coronal plasma frequency in the vicinity of the radio emission regions has been observed<sup>4</sup> to vary with radius approximately according to

$$f_p = 2.8 \times 10^4 (1.55\rho^{-6} + 2.99\rho^{-16})^{1/2}$$

where  $\rho = R/R_\odot$  (ref. 3), while if the sunspot magnetic field source is taken to be an extended magnetic pole at the level of the photosphere, the field on the spot axis is given by<sup>5</sup>

$$f_H = f_{H_0} \left( 1 - \frac{\rho - 1}{[(\rho - 1)^2 + (b^2)^{1/2}]^{1/2}} \right)$$

where  $f_{H_0}$  and  $b$  are the gyrofrequency and magnetic pole radius at the photosphere.

That is

$$f_H = f_H(\rho) = f_H(\rho_p) \text{ or } \Delta f = \Delta f(f_p)$$

Fig. 1a and b. Spectrograph records showing bursts with frequency splitting in which the frequency interval between the components increases with frequency. A type III burst can be seen in the latter part of the record of Fig. 1a.

With a spot field of, say, 2 kG at the photosphere, and with  $b \sim 1/40$ , the frequency interval for  $f_p$  near 20 Mc/s is approximately 100 kc/s, increasing to 300 kc/s for  $f_p = 30$  Mc/s.

Figs. 1a and b show bursts of the type in which frequency splitting was observed by Ellis and McCulloch. These records are chosen to show two or more pairs of bursts occurring at about the same time, and they illustrate clearly that the frequency interval between the components of a pair increases with increasing wave frequency. An analysis of the change in frequency interval with frequency for a number of bursts is shown in Fig. 2. It can be seen that the magnitude of  $\Delta f$  and its range of change with frequency match closely that expected for the plasma theory of the emission. Fig. 1b also shows the characteristically smaller intensity of the lower frequency component of the burst pairs. A microphotometer scan of the spectrographic record of a typical burst (Fig. 3) illustrates this latter property more clearly. It also shows that, as well as being weaker, the low frequency component has a narrower bandwidth, again as would be expected.

Fig. 2. Variation of frequency interval with frequency for 191 bursts (solid circles) observed on March 17, 1966, and 9 bursts (open circles) observed on September 20, 1966.

The evidence therefore suggests that the pairs of bursts observed by Ellis and McCulloch may well be caused by the frequency splitting of plasma radiation in the presence of a magnetic field. In this case, we can use the results of Fig. 2 to calculate the magnetic field intensity corresponding to different values of plasma frequency which are then given by the lower frequency component of each burst pair. In the absence of positional measurements of the source of the radiation in the solar corona, it is necessary to locate the region for which the magnetic field is measured from the estimated variation of plasma frequency with radial distance such as has been given by Wild *et al.*<sup>4</sup>

Fig. 4 shows the variation of gyrofrequency in the corona with radius obtained in this way from Fig. 2. Also shown for comparison is the theoretical variation of gyrofrequency for a unipolar spot field of 2,000 G ( $b = 1/40$ ), and it can be seen that the values derived from the observations vary with radius at a rate which might be expected with this type of magnetic field configuration. The radial distance at which the derived values of  $f_H$  occur depends strongly on the assumed plasma frequency variation. Use of the Baumbach–Allen model would, for example, give  $\rho = 1.5$  for  $f_H = 3$  Mc/s, instead of  $\rho = 2.47$  found using the model illustrated in Fig. 4. This uncertainty could be overcome by measurement of the positions of the sources of the bursts.

The rate of occurrence of the burst pairs appears to be sufficiently high to permit their use in the routine measurement of coronal magnetic fields. During the solar radio outbursts of March 17–21, 1966, for example, a total of 310 groups of bursts were observed, where a group is defined as several bursts occurring at almost the same time. In the following six months, burst pairs were observed on the following dates: June 3, July 20, August 1, August 30, September 6, September 20, even though the high speed records needed to detect them were made only on occasions when solar radio emissions of other types were occurring.

## PLANETARY SCIENCE

### Revision of the Calcite–Aragonite Transition, with the Location of a Triple Point between Calcite I, Calcite II and Aragonite

CONFLICTING reports have been published for the position of the calcite–aragonite phase transition, and two factors contributing to this are the slow solid state reaction kinetics<sup>1</sup> and the problems of quenching the stable assemblage<sup>2</sup>. Bell and England<sup>2</sup> concluded from their experiments that aragonite which formed stably within a wide pressure range (above 600° C) inverted to calcite during the quench. We have recently extended the phase relationships involving a liquid phase in the system calcium oxide–carbon dioxide–water from 4 kbars pressure<sup>3,4</sup> to 40 kbars<sup>5</sup> using a piston-and-cylinder high-pressure apparatus. The liquids in this system are very reactive media, and no problems have been encountered in reaching equilibrium in this and a variety of related systems<sup>6</sup>. Across the calcite–aragonite boundary, the ternary phase assemblage calcite + liquid + vapour undergoes a transition to aragonite + liquid + vapour. In runs completed at pressures well above and well below the phase boundary, aragonite and calcite crystals in the quenched assemblage calcium carbonate + liquid + vapour were positively identified by X-ray and optical properties. The morphology of aragonite crystals coexisting with the ternary liquid is distinct from that of the calcite crystals, and the original shape of the equilibrium phase, aragonite or calcite, becomes frozen into the surrounding liquid during the quench and is thus preserved for microscopic examination. The shape of the carbonate crystals in the quenched assemblage calcium carbonate + liquid + vapour was therefore used to bracket the calcite–aragonite transition boundary down to the solidus temperature at 580° C. X-ray powder diffraction and refractive-index measurements demonstrate that crystals with the morphology of aragonite, in runs close to the transition boundary, have inverted to complexly twinned, biaxial calcite with optic axial angles ranging from near zero up to an estimated 20° (2V for aragonite is 18°). The implications of this observation have been discussed elsewhere<sup>7</sup>.

The morphology of quenched crystals also served as a criterion for distinction between calcite and aragonite when the experiments were extended into the subsolidus region of the system calcium oxide–calcium carbonate–water between 580° C and 400° C. X-ray diffraction patterns were not satisfactory criteria, because aragonite quenched from positions near the transition boundary tended to invert to calcite. Slow reaction rates prevented a satisfactory determination below 400° C in a length of time reasonable for the apparatus. Three reversals were completed across the curve shown in Fig. 1.

The purpose of this communication is to present our revised phase diagram for the system calcium carbonate (Fig. 1), to report the location of a triple point, and to indicate briefly the implications of our results in connex-

ion with the metastable crystallization of aragonite at low pressures. The positions of our runs plotted in Fig. 1 require that the calcite-aragonite boundary changes slope at a pressure of 9.4 kilobars at 480° C. This point lies almost on the best estimate of the boundary for the transition calcite I-calcite II, drawn between the determination of Boeke<sup>8</sup> (point B at 975° C) and Bridgman's<sup>9</sup> determination of the metastable transition at 14 to 15 kbars pressure (points Br). We therefore interpret the change in slope of our experimentally determined calcite-aragonite transition as a triple point between the three phases calcite I, calcite II and aragonite. The aragonite-calcite II transition is closely bracketed by our runs, but considerable variation is possible for the aragonite-calcite I curve between our limited runs at the lower temperatures. We have therefore extended this boundary down through the point determined carefully by Crawford and Fyfe<sup>10</sup> at 100° C.

Previous reports have presented the calcite-aragonite transition boundary in linear, or almost linear, form. The marked change in slope of the calcite-aragonite transition curve at the triple point shown in Fig. 1 can probably be explained by the entropy change involved in the transition of calcite I to calcite II. Assuming that calcite II differs from calcite I by having anion disorder<sup>11</sup>, calculation of the ideal configurational contribution to entropy yields a value of  $\Delta S = 1.4$  Cal/mole °C. This compares well with the value of 1.0 Cal/mole °C required by the change in slope using the Clapeyron equation, assuming that  $\Delta V$  for calcite I  $\rightleftharpoons$  aragonite equals  $\Delta V$  for calcite II  $\rightleftharpoons$  aragonite.

Aragonite forms metastably at the surface of the earth in several environments, and metamorphic aragonite (or calcite inverted from aragonite) has been reported from glaucophane schists<sup>12-14</sup>. It has been assumed that under metamorphic conditions aragonite would not form within the calcite stability field, and the experimentally determined calcite-aragonite transition boundary has therefore been used as a geobarometer; this confirms the conclusion that glaucophane schists were formed at great pressures. Vance<sup>15</sup>, however, has recently discovered widely distributed metamorphic aragonite in pumpellyite-prehnite facies rocks of north-west Washington, and he contends that these rocks could not possibly have been buried to the depths required to produce conditions which correspond to the aragonite stability field shown in Fig. 1. This implies either that the experimentally located calcite-aragonite transition boundary does not represent stable equilibrium, or that considerable tectonic overpressures are developed during metamorphism, or that aragonite

can grow metastably in the calcite field, even under metamorphic conditions. The revised phase diagram presented in Fig. 1 does provide a large pressure-temperature area for the metastable crystallization of aragonite, which includes the near-surface conditions where metastable aragonite is known to grow and also the low-grade metamorphic conditions where Vance reports the formation of aragonite. This is the area between the stable aragonite-calcite I curve and the metastable extension of the aragonite-calcite II curve, which would intersect the temperature axis (at zero pressure) at about 150° C. This large region for metastable aragonite at moderate temperatures and low pressures strengthens Vance's query (personal communication) about the validity of the aragonite-calcite I transition boundary as a geobarometer.

## PHYSICS

### Formation of Alloys at Room Temperature

THE formation of alloys at room temperature was observed by Hund and co-workers, using co-reduction of metal salts by alkaline formaldehyde solution in the case of silver-gold<sup>1</sup>, gold-mercury<sup>2</sup> and silver-mercury<sup>3</sup>. Kulifay<sup>4</sup>, by giving a large number of examples, showed that the formation of intermetallics and other compounds by co-reduction at boiling point, using hydrazine or hypophosphorus acid, is a general phenomenon. Holt<sup>5</sup> also showed that alloys are formed by co-reduction at 50° C using sodium borohydride in the case of platinum-gold, platinum-iridium, palladium-gold, platinum-cobalt, platinum-nickel and platinum-copper.

The purpose of this communication is to show that alloys can also be formed when a metal foil displaces a more noble metal from solution. When silver or copper foil is immersed in certain solution complexes of noble metals it is found that after immersion for 1 or 2 days at room temperature a thin metallic skin forms on the surface of the foil, which exhibits poor adhesion and can be stripped off the foil by means of adhesive tape. The skin can be examined by both X-ray diffraction and X-ray fluorescence spectroscopy. In this way alloy formation was demonstrated in the following examples, in all of which the existence of a continuous series of solid-solution alloys is possible.

Silver foil immersed in a 0.002 molar solution of  $\text{Na}_2\text{PdBr}_4$  and 4 molar sodium bromide for 2 days gave a metallic skin with fluorescence counting rates in a ratio of  $\frac{K\alpha(\text{Ag})}{K\alpha(\text{Pd})} = 1.44$ , and a lattice parameter  $a = 4.00$  Å (pure silver,  $a = 4.0862$  Å; pure palladium  $a = 3.8898$  Å).

In a similar experiment using a 0.002 molar solution of  $\text{Na}_2\text{PtBr}_4$  and 4 molar sodium bromide, the metallic skin

Fig. 1. Phase diagram for the system calcium carbonate. The heavy line passes through our experimental points. The aragonite-calcite I transition passes through our points and the point (C and F) determined by Crawford and Fyfe<sup>10</sup>. The calcite I to calcite II transition was located at point (B) by Boeke<sup>8</sup>, and metastably at points (Br) by Bridgman<sup>9</sup>.

gave counting rates in a ratio  $\frac{K\alpha(\text{Ag})}{L\alpha_1(\text{Pt})} = 4.66$ , and a lattice parameter  $a = 4.03 \text{ \AA}$  (pure platinum,  $a = 3.9231 \text{ \AA}$ ).

In the case of silver and a 0.002 molar solution of  $\text{Na}_3\text{Au}(\text{S}_2\text{O}_3)_2$ , the skin had the appearance of metallic silver and gave counting rates in the ratio  $\frac{K\alpha(\text{Ag})}{L\beta_1(\text{Au})} = 4.71$ .

No measurements of lattice parameters were made because of the close similarity of the values for silver and gold (difference in  $a = 0.0076 \text{ \AA}$ ).

Copper foil immersed overnight in a 0.002 molar solution of  $\text{Na}_2\text{PdBr}_4$  and 4 molar sodium bromide gave a metallic skin with counting rates in the ratio  $\frac{K\alpha(\text{Cu})}{K\alpha(\text{Pd})} = 4.07$ , and lattice parameter  $a = 3.71 \text{ \AA}$  (pure copper,  $a = 3.6150 \text{ \AA}$ ; pure palladium,  $a = 3.8898 \text{ \AA}$ ).

From the lattice parameters it is found that the alloys contain more than 50 atom per cent of the less noble metal.

Attempts to obtain alloys of copper-silver failed, the skins invariably consisting of pure silver. This is not surprising, as the solubility of copper in silver is only 0.3 atom per cent at  $100^\circ \text{C}$  (ref. 6).

### Influence of Oxygen on Photoconduction in Organic Solutions

WE wish to give further results of our work on photoconduction in organic compounds at room temperature. We have already proposed<sup>1</sup> that photoconduction in solutions of triphenylamine in benzene and *n*-hexane requires the absorption of two quanta by the solute. Pilloff and Albrecht have recently shown a similar phenomenon in solutions of *N,N,N',N'*-tetramethyl-*p*-phenylenediamine (TMPD) in 3-methylpentane<sup>2</sup>. Furthermore, our observations show that the magnitude of the photocurrent can be greatly reduced by changing the solvent from benzene to *n*-hexane. We have also described the influence of oxygen on the response of the pure solvent<sup>3</sup>.

Using the same experimental conditions, that is direct current measurements with a 'Teflon' and quartz cell operating with field strengths up to 20,000 V/cm, work has been carried out on solutions of triphenylamine saturated with dry oxygen. In benzene, the photocurrents were reduced to approximately 60 per cent of their usual values, while in *n*-hexane (where photocurrents are about two orders of magnitude less) there appeared to be no significant changes.

Analogous experiments have been carried out using dry nitrogen free from oxygen. In this case, with benzene, the photocurrent values increased by approximately 10 per cent. Again, in *n*-hexane there were no significant changes.

Under all these conditions, it was found that the photocurrent was proportional to the light intensity and to the square root of the triphenylamine concentration, that is, that two photons were required for photoconduction, in agreement with the previous results and our interpretation of them.

The earlier work<sup>1</sup> has also been extended to solutions of anthracene in benzene and *n*-hexane. Apart from an overall reduction in the observed photocurrents to about

5 per cent of the values obtained with triphenylamine, the results already stated have been reproduced. Oxygen and nitrogen saturation produced effects of a different magnitude from those given for triphenylamine, but the results are otherwise similar.

The main features of the photoconductivity of organic solutions are therefore similar when chemically different solutes are used; this has important implications in a more detailed explanation of the process.

As has been suggested elsewhere, for example by Brocklehurst *et al.*<sup>4</sup>, it is reasonable to consider the triplet state as a possible intermediate in a two-photon ionization process, especially in view of its long lifetime. In our work, flash photolysis confirmed our expectation that the oxygen-saturated solution showed no absorption by triplet state triphenylamine, whereas the solution saturated with nitrogen showed a strong triplet absorption. As already mentioned, the photocurrents were nevertheless only in the approximate ratio of 1:2. If the triplet state had been a rate determining intermediate species, we should have expected a far greater reduction of photocurrent on saturation with oxygen.

A further argument against the participation of the triplet state is derived from our observation that, on saturating with nitrogen a solution of triphenylamine in equilibrium with air, the time taken for the triplet concentration after flashing to decay to half its initial value increased from 15  $\mu\text{sec}$  to 340  $\mu\text{sec}$ . If absorption of a photon by the triplet state were needed for ionization, we might therefore expect a very large increase in photoconduction, which was not observed.

These results are also consistent with the observation that, in equally concentrated solutions of triphenylamine in benzene and *n*-hexane in equilibrium with air, the concentration of triplet state triphenylamine after flashing was approximately the same in both solvents, although the photocurrents differed by two orders of magnitude. Regarded in isolation, this change could be ascribed to a corresponding change of mobility or lifetime of the charge carriers in the two solvents. The possibility of attributing part of the change to this cause is not, of course, excluded.

It is interesting to compare these results with those of Johnson and Albrecht<sup>5</sup>, who studied the photoconduction of TMPD in rigid glasses at  $77^\circ \text{K}$ . They, too, deduced a mechanism involving two photons and, among other interesting results, showed that saturation with oxygen reduced the photocurrent to roughly half its value in a helium-saturated rigid matrix. On this basis Johnson and Albrecht concluded that the triplet state of TMPD was not a rate determining step in the production of charge carriers.

On the evidence presented here it seems likely that the triplet state of the solute does not play an important part in photoconduction. The identification of the intermediate, and in particular its lifetime, is an important question. Johnson and Albrecht have suggested that the solvent is involved, and certainly our results for *n*-hexane and benzene could be interpreted as supporting this proposal. There remain, however, many uncertainties which we hope to resolve by further experiment.

### Limits to Resolving Power in Photoelectron Spectroscopy

THE energy spectra of electrons ejected in gaseous photoionization by undispersed radiation from rare gas discharges—a process known as molecular photoelectron spectroscopy<sup>1,2</sup> or, better, spectrometry—have been found to be a rich source of fresh electronic and vibrational data on the states of the resultant ions. As usual when a new technique is being explored, improvements in experimental detail have steadily increased the amount of information accessible in a given case<sup>1-4</sup>. Alternatively the study of more complex substances has been made feasible<sup>1,2</sup>.

During the past 4 years several groups of workers have improved the energy discrimination of the retarding field analyser from the original  $\sim 0.5$  eV to  $\sim 0.1$  eV<sup>2,5-7</sup> and, recently, to  $\sim 0.05$  eV<sup>8,9</sup>.

With this it is possible to discern vibrational fine structure corresponding to the formation of more or less vibrationally excited ions of diatomic molecules of nitrogen, oxygen, carbon monoxide and nitric oxide and of certain excited states of polyatomic molecular ions where only one vibrational mode is excited. When combinations of different vibrational modes occur this resolution is insufficient to separate the various component lines.

We may ask what fundamental restrictions prevent the attainment of better resolution. A practical limit will be set by line broadening in the light source associated with self reversal. Added to this will be the combination of Doppler spread in the emission line ( $\sim 2 \times 10^{-4}$  eV for helium) and in the ionization of the target molecule ( $\sim 5 \times 10^{-5}$  eV) and the contribution that thermal velocity of the ionized molecule makes to the velocity of the ejected electron ( $\sim 2 \times 10^{-3}$  eV). Apart from the reversal effect these may amount together ( $\sim 2 \times 10^{-2}$ ;  $16 \text{ cm}^{-1}$ ) to less than the magnitude of some rotational quanta in X-H type molecules, and we predict that rotational fine structure is in principle capable of being observed in photoelectron spectra, provided that self reversal in the light source does not occur to such an extent as to cause emission line broadening of more than  $10^{-3}$  eV.

Watanabe and Inn<sup>10</sup> have reported reversal in the 584 Å line obtained from a helium discharge leading to two peaks separated by about 1 Å (that is,  $\sim 0.03$  eV). If this applies to the sources used in the present work, clearly no further improvement in resolution is to be expected.

The fractional energy resolving power  $E/\Delta E$  of  $\sim 100$  achieved in the present retarding field analysers has, however, been insufficient to enable us to decide whether

Fig. 1. Photoelectron spectrum excited in (a) argon, (b) xenon, by 21.21 eV photons. Ordinate, counts/sec; abscissa, electron energy (eV).

Fig. 2. A portion of the photoelectron spectrum excited in oxygen gas by 21.21 eV photons. The peaks shown are the first three vibrational components of the highest electron energy band ( $O_2^+X, {}^2\Pi \leftarrow O_2X^+ \Sigma_g^-$ ). The sharper peak superimposed on the  $v' = 0$  component is due to added xenon ( ${}^2P_{3/2}$ ).

Fig. 3. Part of the photoelectron spectrum excited in hydrogen gas mixed with argon by 21.21 eV photons. Ordinate, counts/sec; abscissa, electron energy (eV).

we have reached the limit and still falls far short of the best achieved in other fields of electron velocity analysis<sup>11</sup> (for example,  $\sim 10^6$  using a Wien filter). There seems to be a special problem associated with grid analysers at low electron energies associated especially with surface potential variation over the extensive grid surface.

To avoid this difficulty we have investigated the design of deflexion analysers for photoelectron spectrometry so as to restrict to small slits the metal surface actually in close proximity to the electron flux. The most recent design uses deflexion by  $\pi/\sqrt{2}$  in a radial electrostatic field with a principal orbit radius of 10 cm, all internal surfaces being coated with a uniform layer of benzene soot.

A resolving power  $E/\Delta E$  of 450 was obtained at 9 eV as measured from the photoelectron spectrum of xenon (Fig. 1b). The smallest width at half peak height (0.015 eV) achieved for the peak for argon  ${}^2P_{3/2} \leftarrow {}^1S_0$  (Fig. 1a) is smaller than that which unresolved rotational fine structures should confer on spectra for polyatomic molecules ( $\sim kT$ , 0.028 eV). This result also implies that the light source is substantially free from self reversal effects.

The expected rotational broadening has now been observed in a number of diatomic molecules. In Fig. 2 a portion of the photoelectron spectrum for oxygen has been expanded to show the first four vibrational levels of the  $O_2^+X, {}^2\Pi \leftarrow O_2X^+ \Sigma_g^-$  ionization for which  $r_e$  decreases to  $1.1127 \text{ Å}$  from  $1.2076 \text{ Å}$ . It can be seen that in comparison with the peak due to added xenon the oxygen

peaks are broadened asymmetrically to lower electron energy. This is more than the symmetrical broadening due to spin-orbit splitting (0.024 eV).

The peaks in the hydrogen photoelectron spectrum (Fig. 3) also show marked asymmetrical broadening in this case to higher electron energy consistent with an increase in dimension on ionization ( $r_0$  1.06 Å ← 0.74 Å).

In the case of hydrogen, however, the thermal velocity effect must give a spread of ~20 mV comparable with that expected from rotational energy.

It can be seen from this that large dimensional changes can be expected to be detected from the "shading" of vibrational bands in molecular photoelectron spectra.

Carbon K shell photoelectron spectra have recently been reported by Axelson *et al.*<sup>12</sup> These were obtained using solid samples so that at least part of the line width noted (~1 eV) can be ascribed to lattice effects.

We may expect to find more detailed fine structure associated with small changes in chemical environment in the case of complex substances if the corresponding molecular photoelectron spectra can be obtained. Extensive vibrational fine structure should be absent since the electrons removed may be essentially "non-bonding". Small differences in electron binding energy (0.1 eV) should in principle be readily detectable and lead to a valuable general method for structural diagnosis.

The development of the deflexion analyser was supported by a grant from the Paul Instrument Fund of the Royal Society and will be described in detail elsewhere.

## Antimony-125 Contamination in Antimonial Lead

LEAD containing 4 per cent of antimony (B.S.3909 : 1965) is commonly used for radiation shielding, and when the objective is the reduction of the background response of high sensitivity counting equipment, it is desirable that no radioactive contamination be present. Examples of contamination by <sup>210</sup>Pb (ref. 1) and by <sup>110m</sup>Ag (ref. 2) have been reported.

We have now confirmed the presence of antimony-125 (half-life 2.78 yr) in newly manufactured antimonial lead. Measurements were made with a sodium iodide (TI) crystal with two different cylindrical lead collimators. The first of these consisted of two parts weighing 15.8 kg and 7.5 kg, which were supplied in 1964 and 1965 respectively. The second was in one piece (21 kg) and was also manufactured in 1965. Gamma-ray spectra of the backgrounds of the crystal with the two collimators are shown in Fig. 1 (curves 1 and 2 respectively); the spectrum of the difference of 98 c.p.m. is also shown (curve 3). The two well defined peaks were identified as being due to the pairs of gamma-rays at about 0.43 MeV and 0.6 MeV respectively, which are characteristic of antimony-125. This inference was confirmed by the use of a standardized source of the radionuclide which was measured between pieces of lead 0.1 in. thick, assembled as a mock-up of part of the collimator. The gamma-ray spectrum obtained is shown in curve 4.

Comparison of the counting-rates in the peaks of curves 3 and 4 led to an estimated antimony-125 concentration

Fig. 1. Computer produced plots of gamma-ray spectra. Curves 1 and 2 are background spectra taken with the two collimators, curve 3 is the difference between them, and curve 4 is the spectrum of 13.6 mc. Sb-125 in a lead mock-up of the lower part of one collimator. The logarithmic counting-rate scale covers the range  $10^{-1}$ – $10^2$  c.p.m.

in the 21 kg collimator of  $(3.6 \pm 0.2) \times 10^{-14}$  curie/g of lead or  $(0.90 \pm 0.05) \times 10^{-12}$  curie/g of antimony. The uncertainties shown are those due only to the statistical errors of counting; there may be a systematic error due to the method of calibration, possibly as much as 50 per cent.

The origin of the contamination is unknown. Neither the manufacturers of the collimators nor their suppliers of antimonial lead used antimony-125 in any of their processes. One possible source might be radioactive fall-out from nuclear test explosions; antimony-125 has been measured at concentrations in the range 0.004–0.06 pc./kg of air, and 2–40 pc./l. of rain in the United Kingdom during 1963–65 (refs. 3 and 4). We could not detect antimony-125 in samples of pure antimony supplied in early 1964, although the levels in air and rain during 1963 were quite similar to those during 1964 (refs. 3 and 4), and we have evidence of antimony-125 in antimonial lead bricks which were received in late 1963.

Antimony-125 in lead shielding for low background gamma-ray spectrometers is considerably more of a nuisance than the naturally radioactive lead-210 found in some samples<sup>1</sup>, because of the higher energy radiation emitted. It is also more annoying than ruthenium-103 which has been observed in steel, because of its much longer half-life (2.78 yr compared with 40 days), and somewhat more of a nuisance than ruthenium-106 which has been found in some steels at roughly the same concentration<sup>2</sup>.

## CHEMISTRY

## Complex Formation, Isolation and Carcinogenicity of Polycyclic Aromatic Hydrocarbons

THE carcinogenic activity of some of the polycyclic aromatic hydrocarbons<sup>1,2</sup> present in common materials has focused considerable attention on the properties and isolation of this group of compounds. Many methods for their isolation have been reported which are based, in general, on procedures involving partition<sup>3-6</sup>, adsorption<sup>7-9</sup> or complex formation<sup>9,10</sup>, used either singly or in combination.

The present attempt to develop a more satisfactory method of isolating polycyclic aromatic hydrocarbons stems from the work of Weil-Malherbe<sup>11</sup> who, on the basis of an observation by Brock, Druckrey and Hamperl<sup>12</sup>, investigated the quantitative aspects of the solubilization of a number of polycyclic aromatic hydrocarbons in many different purine solutions. 1:3:7:9-Tetramethyluric acid (TMU) and caffeine were shown to be the most effective purines. Although the phenomenon is not specific to polycyclic aromatic hydrocarbons<sup>13-17</sup>, other compounds such as aromatic amines and heteropolycyclics, which form complexes and are often found in hydrocarbon mixtures, present no difficulty to an attempt to isolate polycyclic aromatic hydrocarbons.

Silica impregnated with caffeine has been used<sup>18,19</sup> in a thin layer chromatographic technique to separate the components of a mixture of polycyclic aromatic hydrocarbons; the preparation of a concentrate of polycyclic aromatic hydrocarbons from petroleum products with high boiling points using aqueous caffeine has been described<sup>20</sup> and counter current distribution with a solvent system containing TMU has been used to separate certain polycyclic aromatic hydrocarbons<sup>17</sup>.

From a consideration of the suggestions put forward for the structure of complexes formed between polycyclic aromatic hydrocarbons and purines<sup>11,21-24</sup> and between polycyclic aromatic hydrocarbons and nitro aromatic compounds<sup>25,26</sup>, it seemed likely that the complexes might migrate under the influence of an electrical potential.

Using curtain paper electrophoresis with platinum electrodes in troughs at the top and bottom of the paper, complexes of polycyclic aromatic hydrocarbons with both caffeine and TMU have been found to migrate readily. Complexes were formed before spotting on the paper; the solvent was a solution of 2 g purine in 90 ml. water-10 ml. ethanol-2 ml. ammonia and the potential and current were 30-35 V/cm and 3-4 m.amp/cm. The twenty-five complexes of polycyclic aromatic hydrocarbons examined all migrated as discrete spots which completely left the baseline. Using the same method, it was later shown that these polycyclic aromatic hydrocarbons could be separated from twelve times their own volume of 'Vaseline'.

In large scale applications of the method, as much as 1 g of hydrocarbon mixtures containing polycyclic aromatic hydrocarbons has been adsorbed on 80-100 g silica and the residue packed into a column 38 mm in diameter. By applying a potential of 1,200-1,500 V to the column and slowly eluting with the solvent already mentioned, almost all the species which could be detected by electron capture during gas-liquid chromatography have been separated from the bulk of the mixture which remained on the column. Furthermore, in experiments in which radioactively labelled polycyclic aromatic hydrocarbons were incorporated in the hydrocarbon mixture, 97-98 per cent of the labelled polycyclic aromatic hydrocarbons were isolated. The exact experimental details of the method, which is now being used with most encouraging results to examine the condensate of cigarette smoke, will be published in the near future.

The nature of the purine/hydrocarbon complexes suggested by Liquori *et al.*<sup>22</sup>, namely a dipole-induced dipole interaction between the polar component (caffeine) and the polarizable component (polycyclic aromatic hydrocarbons), is consistent with the phenomenon which has been demonstrated and used in the present work.

Many attempts have been made to relate the complexing ability of polycyclic aromatic hydrocarbons to their carcinogenic properties, but none has so far been successful. Weil-Malherbe<sup>11</sup> could find no direct relationship but suggested that an affinity between hydrocarbons and the purines in nucleoproteins might cause interference with nucleic acid metabolism. Booth and Boyland<sup>13</sup> also found that carcinogenic polycyclic aromatic hydrocarbons did not differ from non-carcinogenic compounds in their reaction with purines. Liquori *et al.*<sup>22</sup> and Van Duuren<sup>24</sup> have also examined the problem. The rates of electrophoretic migration of all the complexes of polycyclic aromatic hydrocarbons with caffeine and TMU examined are similar and the slight visible differences cannot be related to any carcinogenic properties of the hydrocarbons. It is nevertheless possible that the complexing property of polycyclic aromatic hydrocarbons makes an important contribution to their carcinogenicity, the differences in biological properties resulting from a combination of factors such as molecular size, geometry and general reactivity. Thus the absence of carcinogenic activity in the majority of the polycyclic aromatic hydrocarbons might arise from diffusion and transport difficulties within the cell, lack of ability to adapt to a favourable configuration at the site of action in the cell, or destruction in other biochemical reactions before reaching the site of action. As suggested by Booth and Boyland<sup>13</sup>, the protective action of purines in carcinogenesis may result from their competition with the site of action for the polycyclic compounds.

## BIOCHEMISTRY

## An Error in Model Building

ABOUT a year ago Dr. S. R. Pelc and Miss M. G. E. Welton claimed<sup>1,2</sup> that "it is possible to fit amino-acids stereochemically to their codons". They described how they built models using Courtauld space-filling components, but it was not possible to tell from their very brief descriptions whether their models were stereochemically acceptable. I therefore corresponded with Dr. Pelc and he was kind enough to show me some of their models.

Dr. Pelc produced several examples for me to examine, but I will comment here only on their model of lysine fitted to AAG, as illustrated in the photograph of Fig. 2 of the first of their two papers<sup>1</sup>.

This model is stereochemically unacceptable for the following reasons. (1) The terminal  $-\text{NH}_3^+$  group of the lysine was built as  $-\text{NH}_2$ . (2) In two places (one in the amino-acid, one in the triplet) adjacent methyl groups were in the eclipsed rather than the staggered configuration. (3) In two cases an  $>\text{NH}$ , which should either make a satisfactory hydrogen bond, or at least be free to make one to a water molecule, was pointing directly at a hydrophobic group.

Further inspection revealed that Dr. Pelc and Miss Welton had built all their polynucleotide sequences backwards\*. Their AAG was in fact GAA (which codes glutamic acid). This mistake can be detected by a very careful study of Fig. 2 of ref. 1.

I conclude that the models of Pelc and Welton do not support their hypothesis.

## Adsorption of Octapeptide Hormones on to Lipid Monolayers

THE interaction between lipid monolayers spread on the surface of water, and oxytocin and vasotocin (arginine vasotocin) in the substrate, has been investigated, using a Langmuir surface trough, by studying the changes in pressure produced on injection of various quantities of the polypeptide solution under the film. This technique is similar to that used for the study of the interaction between protein in the substrate and lipid monolayers<sup>1,2</sup>.

In order to avoid contamination the paraffin wax used to coat the trough was freed from surface active impurities by heating with hot 1 normal sodium hydroxide followed by hot 1 normal hydrochloric acid. After thorough washing the wax was recrystallized twice from light petroleum (40°–60°). The water was redistilled with alkaline permanganate, and nitrogen was passed over the covered trough during the experiments.

Samples of cholesterol, stearic acid and lauric acid were all recrystallized to constant melting point using light

petroleum (40°–60°) which itself was 'AnalaR' reagent redistilled. The samples of oxytocin and vasotocin were used as supplied.

Solutions were made of cholesterol (19.3 mg/100 ml.) in benzene, stearic acid (14.4 mg/100 ml.) in light petroleum (40°–60°), lauric acid (10.0 mg/100 ml.) in light petroleum (40°–60°), oxytocin (16.0 mg/100 ml.) in water and vasotocin (10.0 mg/100 ml.) in water.

Using an 'Aglar' microsyringe  $12 \times 10^{16}$  molecules of lipid were injected on to the water surface in the Langmuir surface trough, and the initial pressure of the film was adjusted to 10 dynes/cm in the case of cholesterol, and 2 dynes/cm in the case of the fatty acids. The polypeptide solution was injected through the lipid monolayer and the pressure of the film increased, reaching a maximum value after 50 min. This increase in pressure was measured by a horizontal torsion wire, which was sensitive to 0.02 dynes/cm, and was used to obtain isotherms for the adsorption of peptide on to the lipid monolayer (Fig. 1). All isotherms obtained were similar, showing two marked discontinuities which are believed to represent stable surface structures (Fig. 2). Details of the results obtained are listed in Table 1.

Structure A, which is proposed for the final structure of the adsorbed film, is based on the fact that the chemical structures of oxytocin and vasotocin contain rings with six peptide bonds:

Vasotocin

Oxytocin

Previous work<sup>1,2</sup> supports the idea that polar groups of the lipid associate with peptide links in protein. It is therefore reasonable to suppose that the final structure indicated by a 6 : 1 lipid to polypeptide ratio represents a ring of six lipid molecules adsorbed at each peptide link in the ring of the hormone—the ring structure being one of the essential structural features for physiological activity<sup>3</sup>.

Structure B is proposed as the intermediate structure based on a 21 : 1 lipid to polypeptide ratio, found for both cholesterol and the fatty acids. Because these two types of lipid are very different in size, the association must

Fig. 1. The variation of surface pressure increase  $\Delta\pi$ , with volume of vasotocin solution injected through a monomolecular layer of cholesterol ( $12 \times 10^{16}$  molecules) at a surface of water.

Fig. 2. Proposed surface structures of octapeptide hormones adsorbed on to lipid monolayer.

depend on a definite array of lipid rather than a network of peptide underneath.

The initial adsorption, which accounts for the highest increment of pressure, seems to impose the hexagonal unit structure on the lipid monolayer, possibly as a result of adsorption of both ring and tail of the hormone. The three peptide long tail unit could occupy the space between each polypeptide ring unit. The additional increase in pressure probably results as lipid molecules are removed from the centre of each hexagonal unit to form new units as the final structure forms.

If the lipid monolayer is taken as a suitable basic model of cell membranes, then it may be supposed that the effect of such structures forming in cell membranes would be to provide effective "pores" to facilitate the movement of water and other small molecules. Such biological effects of the octapeptide hormones have been demonstrated<sup>4,5</sup>, which are consistent with those expected if "pore" size had been changed.

### Sterols from the Fruit and Seed of Tomato

THE quantity of carotenoid that a tomato fruit can synthesize depends on its genetic background. The total for a red,  $r^{+}t^{+}$ , or tangerine,  $r^{+}t$ , may run as high as 200  $\mu\text{g/g}$  of fresh fruit if the colourless polyenes, phytoene and phytofluene, are included. The ghost genotypes, for example  $r^{+}t\ gh$ , may even run higher. By contrast, comparable figures for yellow,  $rt^{+}$ , range from 2 to 5  $\mu\text{g}$ .

In the early stages of carotenoid and sterol synthesis, intermediates are the same, available to both unless different sites are involved. We were therefore interested to determine whether some of the numerous genes affecting carotenoid production would likewise affect the sterols. So far as we are aware, apart from the related tomatidine, there have been no studies of the tomato sterols. They are not listed by Stoll and Jucker<sup>1</sup> in their chapter "Phytosterine, Steroidsaponine und Herzglykoside". Of the common phytosterols, the presence or absence of ergosterol can be ascertained from the ultra-violet absorption spectrum, and the most frequently found are the sitosterols and stigmasterol (compare Heftmann and Mosetig<sup>2</sup>). As Shoppee<sup>3</sup> has noted, the sitosterols are usually difficult to purify and identify.

Fruit and seed of the following tomato genotypes were examined separately: red, yellow, tangerine, apricot, red-ghost, yellow-ghost, tangerine-ghost.

Samples of fruit (500 g) and seed (5–10 g) were exhaustively extracted with acetone, and the digitonides were prepared in accord with the outline given by Stoll and Jucker<sup>1</sup>. The precipitates were dried under vacuum and weighed. Results are shown in Table 1.

The free sterols were then obtained by boiling in xylene, and the digitonin removed by centrifugation. The xylene supernatant was then evaporated to dryness, and the residue was acetylated.

Thin-layer chromatography gave spots indistinguishable from those for sitosterol and stigmasterol, but these two could not be effectively distinguished from each other. Adsorbents tested included alumina, kieselguhr G and silica gel<sup>4,5</sup>.

Gas liquid chromatography was more effective on the acetylated products. The acetates of stigmasterol and  $\beta$ -sitosterol melted at 144–5° and 118°, respectively; those of seed and fruit sterols varied from (111–12°) to (116–20°). Samples of about 0.4 mg in 0.04 ml. were injected in a 'Loenco' gas chromatograph. A 5 ft. column of 10 per cent silicone grease 'DC' on 'HMDS' treated 'Chromosorb W', 80/100 mesh, was operated at 283°. The helium flow at 20 lb. pressure was about 75 ml./min. Slower flow rates or lower temperatures did not give sharp peaks.

Table 1. DIGITONIDES FROM FRUIT AND SEED OF TOMATOES OF DIFFERENT GENOTYPES

Tomato	Fruit mg/100 g	Seed mg/g
Red	5.2, 5.0, 8.6, 10.2, 10.8, 11.7	3.9, 3.8
Yellow	9.0, 10.5, 11.6, 8.1	6.4
Tangerine	9.4, 7.6, 11.0, 9.5, 7.8, 12.1	5.6
Apricot	14.1, 12.8	3.9, 3.3, 4.7
Red-ghost	9.2	—
Yellow-ghost	8.1	—
Tangerine-ghost	13.1	—

Under the foregoing conditions, all tomato samples gave three sharply defined peaks with retention times of 140, 165 and 180 sec. Authentic samples of ergosterol and soybean sitosterol, stigmasterol and  $\beta$ -sitosterol were acetylated and used for comparison.

The soybean sitosterol also gave three peaks, the main one indistinguishable from that for stigmasterol and the second peak of the tomato. The  $\beta$ -sitosterol co-chromatographs with the third peak.

Characteristically, all fruit samples gave peak heights  $\text{II} > \text{III} > \text{I}$ , whereas the seeds gave the order  $\text{III} > \text{II} > \text{I}$ . Peak II was enhanced by the addition of stigmasterol, peak III by  $\beta$ -sitosterol.

It seemed likely, therefore, that peak III was caused by  $\beta$ -sitosterol; peak II might be stigmasterol; and peak I might (we speculated at first) be caused by dihydro  $\beta$ -sitosterol, a common minor component of the sterol mixture<sup>1</sup>, but it is more probably a campesterol<sup>6,7</sup>.

Stigmasteryl acetate readily forms a characteristic tetrabrom derivative and crystallizes within a few minutes, melting point 195–6°. The tomato sterol derivatives crystallized much less rapidly; the fruit sterol melted at 184–5° after recrystallization, the seed sterol at 182–3°. Bromination was therefore inconclusive.

Samples of the free sterols were analysed in the mass spectrometer and comparisons were made with stigmasterol,  $\beta$ -sitosterol, soybean sterols and dihydro  $\beta$ -sitosterol prepared by hydrogenation of  $\beta$ -sitosterol.

As would be anticipated, stigmasterol gave a prominent peak, for a molecular ion of mass 412;  $\beta$ -sitosterol, 414; dihydro  $\beta$ -sitosterol, 416. The  $\beta$ -sitosterol sample also yielded a small peak at 400, suggestive of campesterol, and a still smaller one at 416. The soybean sample gave peaks at 412, 414 and a smaller one at 400.

The main peaks for the tomato fruit and seed sterols were at 414 and 412; additional peaks were noted at 400, and also at 416 and at 428 and 426. The presence of  $\text{C}_{30}$  sterols of mass 428 and 426 raises an interesting question as to their relationship to the  $\text{C}_{28}$  sterols of mass 414 and 412.

The two principal sterol components of the tomato fruit in all probability correspond with stigmasterol and  $\beta$ -sitosterol, the former comprising 60–70 per cent of the mixture. In the seed, the same two components are found with the proportions reversed. Campesterol is probably responsible for the first peak from the gas liquid chromatography column, and there is evidence for traces of  $\text{C}_{28}$  sterol of mass 416, and  $\text{C}_{30}$  sterols of mass 426 and 428.

It may be added that squalene was isolated from the unsaponifiable fractions of all extracts by both thin-layer and gas chromatography. It was present in concentrations of about 1 p.p.m.

As shown in Table 1, the genes controlling carotenoid synthesis have no effect on the sterols, either in the fruit or in the seed.

We thank the U.S. National Science Foundation for a grant. We also thank Professors A. L. Burlingame and W. G. Dauben for their help in securing and interpreting the mass spectra, and Mr. J. Jen for preparing the dihydro  $\beta$ -sitosterol and for other assistance.

## Energy Terms of Oxygen and Riboflavin— a Biological Quantum Ladder?

DHRE AND CASTELLI<sup>1</sup> reported the delayed emission of riboflavin at approximately 6000 Å and described it as a phosphorescence. Szent-Gyorgyi<sup>2</sup> found that if the phosphorescence was to be seen dissolved oxygen had to be present. Steele<sup>3</sup> was able to measure the emission spectrum of the riboflavin phosphorescence, maximum at 6030 Å, only in the presence of dissolved oxygen. Shiga and Piette<sup>4</sup> using electron paramagnetic resonance spectroscopy confirmed the oxygen effect and suggested that the phosphorescent emission was prolonged by an inhibition of the non-radiative triplet-singlet transition. As this effect of oxygen, increasing the lifetime of a triplet energy term, is in direct contrast with its well known marked quenching of molecular phosphorescences by shortening the lifetimes of the triplets, presumably by paramagnetic perturbation of the triplet-singlet transition, we have looked for an explanation of the paradoxical increase in the triplet lifetime of riboflavin in the presence of oxygen.

Ogryzlo<sup>5</sup> has discussed the work which assigns the strong visible absorption bands of liquid oxygen as due to a single photon simultaneously elevating two electrons on different oxygen molecules to excited singlet states. A similar double transition event has been reported by Dijkgraaf<sup>6</sup> in a solution of naphthalene and oxygen in which a 3500 Å photon was found simultaneously to excite oxygen to its lowest metastable singlet state (half life  $3.6 \times 10^3$  sec for the unperturbed oxygen ( $^1\Delta_g$  molecule<sup>7</sup>) and naphthalene to its lowest metastable triplet state,  $^3B_{2u}$ . The mechanism converse to the simultaneous absorption of one photon by two molecular species has now been well documented<sup>8</sup> as applying in many chemical reactions which evolve molecular oxygen in excited singlet states. In these instances a pair of excited oxygen molecules react to emit the sum of the excited state energies of the two molecules as one photon of light.

As an extension of these observations we suggest that absorption of light by a riboflavin-oxygen system, at low temperatures, results in a simultaneous electronic transition, induced by one photon, of riboflavin to its lowest excited triplet level and of oxygen to its lowest excited singlet level; equation (1):

We suggest then that the 6030 Å emission from the riboflavin-oxygen system, designated until now as a phosphorescence, is in fact a bimolecular phosphorescence, recombining the energies of the excited metastable states of oxygen and riboflavin in one photon, the reverse of equation (1). In addition, the reaction of equation (2) would account for the apparent prolongation of the riboflavin triplet lifetime by oxygen<sup>4</sup>, that is, the excited singlet oxygen with its extremely long lifetime, functions as an energy reservoir.

This mechanism does not require the formation of any specific riboflavin-oxygen complex, but depends only on the match of the electronic energy terms of the two species. Conceivably, a similar match of energy terms could account for the prolonged riboflavin triplet lifetime induced by cupric ions reported by Shiga and Piette<sup>4</sup> on the basis of electron paramagnetic resonance experiments.

We consider these reflexions to have important implications for biology. If the proposed mechanism is valid it means that the actual triplet energy term of riboflavin lies 1 eV lower than its present assignment of 2 eV. This places it at an energy level equivalent to, or "resonant" with, the lowest excited singlet term of molecular

oxygen, namely, 1 eV. This is a potential drop that can be attained in biological redox energetics and provides a possible mechanism for the generation of excited molecular oxygen. Furthermore, the standard free energy available from perhydroxyl radical interactions,  $2 \cdot \text{O}_2\text{H} \rightarrow \text{HOOH} + \text{O}_2$ , of 1.62 eV (37.5 kcal, ref. 9) equals that of the higher excited energy term of molecular oxygen,  $^1\Sigma_g^+$ , and provides a *raison d'être* for double flavin interactions at the intermediate semiquinone redox level in biological reactions<sup>10-12</sup>. The generation of excited molecular oxygen may account for the ubiquitous distribution of catalase in the body, particularly in the microbodies associated with the endoplasmic reticulum<sup>13</sup>. Support for this thesis is inherent in the observation of Steele<sup>3</sup>, who obtained flashes of light when catalase was injected into an HOOH-riboflavin solution.

It appears probable that biochemical mechanisms exist for the generation of one or the other of the excited molecular oxygen species,  $^1\Delta_g$  or  $^1\Sigma_g^+$ , which may then react in concert by the energy term combinations described by Khan and Kasha<sup>14</sup> to provide a spectrum of available energies an order of magnitude larger than the standard free energy of hydrolysis of adenosine triphosphate. As suggested by Stauff<sup>15</sup> and Khan and Kasha<sup>14</sup>, excited molecular oxygen species may provide the energetics for the display of bioluminescent emissions throughout the visible spectrum. Certainly the phenomenon of bioluminescence is the evidence *par excellence* that biological systems can mobilize energies of such magnitude. The high quantum yields of bioluminescent emissions<sup>16</sup> indicate that the excited molecular oxygen species, if so generated, are "coupled" mechanistically to the molecular oscillators (luciferins) to which the energy is transferred.

In summary, by the generation of electronic excitation states from the oxidation exothermicities of substrates produced by photosynthesis, photochemical energies of the near ultra-violet-visible-near infra-red electromagnetic spectrum, by way of the oxygen quantum ladder, are made accessible, independent of sunlight, to biological systems in the animal kingdom. The ability of these biological systems to mobilize accessible potentials of 1 eV to levels as high as 3.25 eV seems to be evidence for this mechanism.

Critical experiments suggested by this theoretical analysis are in progress.

## Synthesis of a Plant Hormone by the Salivary Apparatus of Plant-sucking Hemiptera

As a result of investigations into the galls and other plant deformations caused by Hemiptera, the salivary glands of aphids have been claimed to convert tryptophan to  $\beta$ -indolyl acetic acid (IAA) *in vitro*<sup>1</sup>, and their saliva has been shown to contain varying amounts of this plant hormone<sup>2</sup>. Experiments have demonstrated the ability of a mirid and a leafhopper to transfer ingested IAA to the salivary glands and saliva<sup>3</sup>, but the salivary system of all the phytophagous Hemiptera may have the requirements for the synthesis of IAA from endogenous metabolites<sup>4</sup>. Thus tryptophan is known to be converted to IAA by quinones<sup>5</sup> such as would arise by the action of the insects' own salivary polyphenol oxidase<sup>6</sup>; and both tryptophan and a substrate for the enzyme have been found in the secretions of the salivary glands<sup>7</sup>. The following is an account of experiments designed to test the possible synthesis of salivary IAA in Hemiptera. Two insects were used: *Eumecopus punctiventris* Stål (Pentatomidae) and *Elasmolomus sordidus* (F.).

Injection of 1.5  $\mu\text{C}$  of DL-3-phenylalanine-1-<sup>14</sup>C in 3  $\mu\text{l}$ . of Martignoni and Scallion's salt solution<sup>8</sup> (without ascorbic acid) into the haemolymph of larvae of *Eumecopus* at the fifth instar resulted in the appearance in the salivary glands, 1-1.5 h later, of subequal quantities of labelled phenylalanine and other radioactive compounds with the same  $R_F$  as dihydroxyphenylalanine (DOPA). This was revealed by autoradiography of thin layer chromatograms (silica gel G (Merck), developed in butanol/acetic acid/water (77:6:17): entire, rinsed glands were placed on the origins). Most of the radioactivity had disappeared from the salivary glands or been incorporated into insoluble compounds 2 h after the injection, but a labelled compound with the same  $R_F$  as tyrosine could still be identified. The haemolymph, at this time, still showed the presence of labelled phenylalanine, with only traces of derivatives. The results of this experiment support an earlier suggestion that DOPA is the substrate for the salivary polyphenol oxidase<sup>7</sup>; and it indicates that phenylalanine is a precursor.

Fig. 1. Sunflower plant showing swollen and split stem, epinasty, and distortion, caused by feeding by *Elasmolomus sordidus* adults after they had been injected with tryptophan and phenylalanine; untreated insects produced slight distortion at most.

Further experiments were done with the much smaller *Elasmolomus*, the adults of which have a volume of haemolymph, estimated by dye dilution<sup>9</sup>, of about 6  $\mu$ l. After injection of the adults with 0.5  $\mu$ c. labelled phenylalanine, thin layer chromatography with methylethylketone/propionic acid/water (3:1:1) indicated that tyrosine was the main oxidation product in the salivary glands. In another experiment, 0.5  $\mu$ c. DL-tryptophan(methylene-<sup>14</sup>C), in 1  $\mu$ l. salt solution containing 2  $\mu$ g L-phenylalanine (unlabelled), was injected into each of thirty *Elasmolomus*. About 3 h after the first injection, the salivary glands (including the accessory gland and ducts) were dissected out, rinsed in distilled water, and immediately homogenized at 35° C. The dissections were completed in 1 h, and the accumulated brei was then immediately placed on a chromatogram, which was developed in methyl-acetate/isopropanol/25 per cent ammonia (45:35:20). Autoradiography revealed that, in the brei, a small amount of the tryptophan had been converted to a labelled compound with the same  $R_F$  as IAA.

At the pH of the brei (6.5) spontaneous conversion of tryptophan to IAA could not be demonstrated, so we assumed that some of the labelled tryptophan was converted to IAA under the influence of quinones produced from tyrosine or DOPA in the salivary glands by the polyphenol oxidase released from the accessory gland<sup>6</sup> during homogenization. Chromatography of the haemolymph of untreated insects showed that free tryptophan and phenylalanine are normal constituents; thus we consider it likely that synthesis of IAA occurs naturally during the salivation of these insects. Because amino-acids injected into the haemolymph appear in greater concentration in the salivary glands and saliva of Heteroptera shortly afterwards (unpublished data), it seemed possible that insects injected with tryptophan and phenylalanine would produce more salivary IAA than normal ones. In order to test this prediction, small flakes of dried agar, containing tryptophan and phenylalanine (about 3  $\mu$ g of each per insect), were inserted into the abdomens of *Elasmolomus*, and these were confined on sunflower seedlings for 3 days. Over the next 2 weeks, these seedlings developed swelling and splitting of nodes, epinasty, and crooked stems (Fig. 1), that is, all the symptoms that could be simulated by localized applications of IAA. Untreated insects and insects with inserts of agar alone produced no such obvious abnormalities.

### Metabolism of Dihydroxyphenylalanine in Human Subjects

THE metabolism of dihydroxyphenylalanine (DOPA; I,  $R=H$ ) may be very complex. By analogy with other amino-acids, degradation may involve decarboxylation (route A) or transamination (route B), with methylation of the 3-hydroxy group possible at any stage. The principal metabolite in normal human urine appears to be homovanillic acid (HVA; III,  $R=CH_3$ ), and excretion of small

amounts of 3-methoxytyramine (II,  $R=CH_3$ ) clearly points to the operation of route A.

Recent observations<sup>1,2</sup> suggest, however, that route B is also operative, particularly in pathological conditions. The main evidence in support of this is the occasional excretion of 4-hydroxy-3-methoxyphenyllactic acid (VLA; V,  $R=CH_3$ ), particularly by subjects producing excessive quantities of DOPA. A search for this acid in normal urines, even using new techniques (unpublished) of greatly enhanced sensitivity, has not so far been fruitful. The corresponding pyruvic acid (VPA; IV,  $R=CH_3$ ) appears, however, to be invariably excreted in small quantities. It has been suggested<sup>2</sup> that the excretion of VLA and VPA in pathological cases involves not only the degradation of larger quantities of DOPA but also an impairment

to route A (or possibly to the conversion of IV to III) leading to an unusual dependence on route B.

In order to throw further light on this subject, I have investigated the metabolism of DOPA and some allied compounds. Urines collected at intervals of 2 h before and after oral administration of suitable doses (50–200 mg) to normal male subjects were examined by paper chromatography. I sought increases in the excretion of methylated compounds (II–V,  $R=CH_3$ ) only; previous workers<sup>3</sup> have detected increased excretion of HVA after administration of DOPA.

Ingestion of DOPA led to the excretion of much apparently homogeneous 3-methoxytyramine. A mixture of acids was formed which could not be resolved completely, but which appeared to consist of HVA heavily contaminated with the isomeric 3-hydroxy-4-methoxy compound. Only doubtfully significant increases in VPA, two or three times the single control values, were observed.

When VPA was fed, much was excreted unchanged, but a moderate increase in HVA was observed and VLA could easily be detected, although it was obviously formed in very small amounts. The increase in HVA was observed in urines heated under acid conditions to destroy VPA, which decomposes to give some HVA when chromatographed. That HVA was formed directly from VPA, rather than by reamination of the pyruvic acid and hence by route A, was indicated by the lack of increase in the excretion of 3-methoxytyramine. Ingested VLA was mainly excreted unchanged, but moderate increases in VPA and HVA were also noted.

It is clear from the formation of the HVA isomer after DOPA that feeding experiments cannot be counted on to reflect normal metabolic processes accurately; urinary HVA usually appears to be homogeneous. The experiments do, however, support the view that route A is the predominant pathway in normal subjects and the rather poor yield of HVA from VPA suggests that the former acid is derived almost entirely from DOPA by way of this route. The experiments also confirm the formation of VLA from VPA. This reaction is reversible, however, and the yield of VLA from VPA was surprisingly low. This observation is compatible with the detection of VPA but not VLA in normal urines. It seems probable

that the reduction of VPA occurs much more readily in pathological urines, but it is also possible that direct conversion of amino-acid (I) to lactic acid (V) might occur, or that VLA might be derived predominantly from 3:4-dihydroxyphenylpyruvic acid (IV,  $R=H$ ).

### Identification of L-Ornithine and $\delta$ -Amino-succinyl Ornithine in Cell Wall Hydrolysates of *Lactobacillus cellobiosus*

UNTIL recently, 2,6-diaminopimelic acid and lysine were the only diamino-acids known to occur in the murein (mucopolysaccharide) of bacterial cell walls<sup>1,2</sup>. Other diamino-acids have now been found to occur in the cell walls of several micro-organisms. Diaminobutyric acid<sup>3</sup> and 3-hydroxy-2,6-diaminopimelic acid<sup>4</sup> are present in the cell walls of *Corynebacterium tritici* and *Ampullariella regularis*, respectively, and ornithine, both D- and L-configuration, in the plant pathogenic corynebacteria *C. betae*, *C. flaccum-faciens*, *C. poinsettiae*<sup>5</sup>, in *Micrococcus radiodurans*<sup>6</sup>, and in *Lactobacillus bifidus* var. *pennsylvanicus*<sup>6</sup>.

In agreement with earlier investigations<sup>7,8</sup>, the examination of the cell wall composition in thirty species of the genus *Lactobacillus* showed that diaminopimelic acid (in *L. plantarum* only), lysine, alanine, glutamic acid and aspartic acid were present as constituent amino-acids of the murein. In *L. cellobiosus* ATCC 11739, however, ornithine was found instead of lysine.

The cell walls were prepared by shaking the cells with glass beads (homogenizator of Bühler, Tübingen) and by digestion with trypsin. For the removal of teichoic acid the cell walls were extracted with trichloroacetic acid in the cold, and the polysaccharides were extracted by heating with formamide at 160° C for 2 h. The resulting murein

Fig. 2. Two-dimensional paper chromatogram of a hydrolysate (4 normal hydrochloric acid, 16 h, 100° C) of *L. cellobiosus* cell walls in the solvent system (a) and (b).

was about 80 per cent pure, the main impurities being polysaccharides.

Based on glutamic acid, the molar ratio of the amino-acids and amino-sugars in this preparation is: MurNAc: GlcNAc: Ala: Glu: Orn: Asp = 1:1:1,7-1,8:1:1:1.

Ornithine has been identified by column chromatography (amino-acid analyser—Bender u. Hobein, München) and by paper chromatography in the following solvent systems: (a) isopropanol:glacial acetic acid:water 75:10:15; (b)  $\alpha$ -picoline: ammonia (specific gravity 0.88):water 70:2:28; (c) methanol:water:pyridine:hydrochloric acid 32:7:4:1, a solvent system especially suitable for the separation of diamino-acids<sup>9</sup>; (d) butanol:glacial acetic acid:water 4:1:5, upper phase; it was also identified by determination of the absorption spectrum of the reaction product of ornithine with acid ninhydrin<sup>9</sup>. For this purpose, the hydrolysate of the cell walls was chromatographed on paper using system (c), and ornithine was eluted with water after being localized by spraying a strip of the chromatogram with ninhydrin. It was then re-chromatographed in solvent system (b) to remove pyridine hydrochloride which originated from solvent system (c). An authentic sample of ornithine and the eluate were treated identically with acid ninhydrin according to Work<sup>9</sup>, and the absorption spectra were measured in a recording spectrophotometer. As shown in Fig. 1, both absorption spectra are identical and show maxima at 472 and 516 m $\mu$  respectively.

The configuration of ornithine was determined enzymatically. L-Ornithine was converted to L-citrulline in the presence of carbamoyl-phosphate and ornithine carbamoyl-transferase using a cell-free extract of *Streptococcus lactis* which was grown in arginine medium as an enzyme<sup>10</sup>. The assay was performed essentially in the way described by Work<sup>5</sup>. On the basis of this estimation, 92 per cent of ornithine was converted to citrulline, thus indicating that ornithine from *L. cellobiosus* cell walls has the L-configuration.

On two-dimensional paper chromatograms of hydrolysates (4 normal hydrochloric acid, 100° C, 16 h) of the murein of *L. cellobiosus* in systems (a) and (b), a hitherto unknown spot appeared in addition to the usual amino-acids and amino sugars (Fig. 2, compound A). Compound A has been identified as a derivative of ornithine. When cell walls of *L. casei* are hydrolysed under the same conditions  $\epsilon$ -(aminosuccinyl)-lysine is found in the hydrolysate. This compound is formed during acid hydrolysis by cyclization to a succinimide derivative, when aspartic acid is bound by one of its carboxyl groups to the  $\epsilon$ -amino group of lysine<sup>11</sup>. Under more vigorous conditions of hydrolysis, for example, 6 normal hydrochloric acid, 110° C, 18 h,  $\epsilon$ -(aminosuccinyl)-lysine is hydrolysed yielding lysine and aspartic acid<sup>12</sup>. Correspondingly, compound A yielded aspartic acid and ornithine. Under mild alkaline conditions of hydrolysis,

Fig. 1. Absorption spectra of the reaction products of authentic ornithine (curve A) and ornithine from *L. cellobiosus* cell walls (curve B) with acid ninhydrin.

the succinimide ring of  $\epsilon$ -(aminosuccinyl)-lysine is split under the release of the two peptides  $N^6$ -( $\alpha$ -aspartyl)-lysine and  $N^6$ -( $\beta$ -aspartyl)-lysine<sup>12</sup>. If compound A is a homologue of  $\epsilon$ -(aminosuccinyl)-lysine, alkaline treatment of the compound should yield  $N^5$ -( $\alpha$ -aspartyl)-ornithine and  $N^5$ -( $\beta$ -aspartyl)-ornithine. Compound A was therefore incubated for 1 h at room temperature in 0.8 normal barium hydroxide, the solution was neutralized with normal sulphuric acid, and the precipitate was centrifuged off. Chromatography of the supernatant in systems (b) and (d) showed the presence of two ninhydrin-positive compounds which were both different from compound A. One of these compounds was chromatographically identical with  $N^5$ -( $\alpha$ -aspartyl)-ornithine, which has been synthesized for comparison by the method described for the synthesis of  $N^6$ -( $\alpha$ -aspartyl)-lysine by Swallow *et al.*<sup>12</sup>. It is therefore likely that compound A is identical with  $\delta$ -(aminosuccinyl)-ornithine and is probably formed during acid hydrolysis as described for  $\epsilon$ -(aminosuccinyl)-lysine<sup>11,12</sup>. The occurrence of  $\delta$ -(aminosuccinyl)-ornithine in the hydrolysate of murein in *L. cellobiosus* indicates that aspartic acid is linked to the  $\delta$ -amino-group of ornithine and represents a cross-linking molecule like the pentaglycine in the murein of *Staphylococcus aureus*<sup>13</sup>.

### Effect of Ionic Strength on the Apparent Anti-coagulant Activity of Bovine Heparin

THE preparation of a series of fractions<sup>1</sup> of commercial bovine heparin with varying molecular weight and biological activity by solvent (ethanol-water) elution and by Ecteola column chromatography gave us an opportunity to investigate the role of electrostatic interactions on the anti-coagulant activity of these fractions.

To examine the effects of molecular weight, inactivation and method of preparation on the sensitivity of anti-coagulant activity to ionic strength, the biological activity of various preparations of heparin was measured by a modified USP XVI method in the presence of increasing concentrations of sodium chloride. Preliminary measurements were made to determine the effect of high concentrations of sodium chloride on clotting time. At concentrations of sodium chloride greater than 1.25 molar, the clotting time is increased and the appearance of the final clot alters from opaque to transparent. At high concentrations of salt (3.0 molar) the polymerization of fibrinogen to fibrin is significantly retarded<sup>2</sup> and the configuration of the fibrin at the gel point was found to vary with the ionic strength<sup>3</sup>. The normal opaque clot was used as the end point in these experiments.

The sensitivity of the measured anti-coagulant activity to increasing concentrations of sodium chloride between 0.25 and 1.25 molar appears minimal for the fractions (Fig. 1) of heparin of high and low molecular weight and of high and low anti-coagulant activity prepared on

Ecteola. The anti-coagulant activity of unfractionated heparin is not sensitive to salt concentrations up to 0.5 molar sodium chloride. At higher salt concentrations there is a precipitous drop in activity, and a large decrease occurs between 0.5 and 1.0 molar sodium chloride. The fractions of high molecular weight prepared by alcohol elution behave in a similar manner. The fractions of low molecular weight are relatively less sensitive to increase in ionic strength. Partially inactivated heparin behaves like the unfractionated preparation, the largest decrease occurring above 0.75 molar. The anti-coagulant activity of inactivated heparin (prepared by incubating unfractionated heparin in hydrochloric acid at pH 2.0 and 38° C for 1–7 h) which retains only half its original activity, but without any significant change in molecular weight or viscosity, is relatively insensitive to increasing ionic strength. Inhibition of clotting by increasing salt concentration has been demonstrated<sup>2</sup>. Prolonged clotting time in the test for heparin activity would be recorded as an apparent high biological activity. Because no change or decrease in apparent biological activity was found below  $\mu = 1.25$ , the overall mode of action of sodium chloride in the presence of heparin is not in the fibrinogen-fibrin conversion.

Because the range of ionic strength in which the decrease in apparent activity is observed occurs above 0.5 molar, it

Fig. 1. Effect of ionic strength of sodium chloride on the anti-coagulant activity of heparin preparations. Ecteola fractions 7-6A and 7-3A have molecular weights of 15,680 and 8,460, respectively. Alcohol fractions have molecular weights of 11,940 (47B), 5,540 (61B) and 13,660 (43B). The unfractionated material had a molecular weight of 8,940. The molecular weights were determined at pH 2.5 in 0.5 molar sodium chloride using sedimentation equilibrium. x, Ecteola 7-6A; □, Ecteola 7-3A; ○, alcohol 47B; Δ, alcohol 61B; ●, alcohol 43B; OH2 ■, unfractionated; ▲, inactive 126 u/mg; ▽, inactive 77 u/mg.

is not expected that the ionic atmosphere of the polyelectrolyte or its configuration can play a major part in the effects observed. These effects have been observed for sodium desoxyribonucleate at lower ionic strengths, about 0.05<sup>4</sup>.

If the interaction of the polyanion and its substrate were electrostatic, an apparent decrease in biological activity would be observed with increasing ionic strength, as the anion competed with the polyanion for active sites. In parallel experiments Mora<sup>5</sup> found that the inhibition of ribonuclease activity on ribonucleic acid by polyglucose sulphate was strongly dependent on ionic strength. The inhibition was less efficient at high salt concentrations. The interaction of trypsin and polyglutamic acid was also found to depend on ionic strength, indicating an electrostatic interaction<sup>6</sup>.

Several workers have investigated the interaction of heparin with macromolecules. Scott<sup>7</sup> measured the sensitivity of the solubility of quaternary amine salts of aliphatic acids complexed with heparin to varying concentrations of sodium chloride, by determining the minimal concentration of potassium chloride necessary to solubilize the polymer complex. The change in solubility is sudden and occurs in a narrow range of electrolyte concentration. Heparin complex of low activity was most easily soluble while that of higher activity was solubilized at higher concentration of potassium chloride. Similarly, heparin of low molecular weight was solubilized at a lower ionic strength than the heparin of higher molecular weight. The ability to fractionate heparin into widely different molecular weights with the cellulose ion exchanger ECTEOLA is dependent, in part, on electrostatic interactions.

The interactions in the complex plasma test system involved in the evaluation of anti-coagulant activity have not been clarified, and the chemistry of the fibrinogen-fibrin conversion has itself not been elucidated<sup>8</sup>. Clot formation results when thrombin and fibrinogen interact to form the fibrin clot. Various anions, including chloride, *M*-benzene disulphonate and isopropyl sulphonate<sup>2</sup>, react either with thrombin or fibrinogen to retard clot formation, while isopropyl sulphonate, aurine, and *M*-benzene sulphonate are ineffective. Polyanions, including heparin<sup>9</sup>, ribonucleic acid<sup>10</sup> and polyglutamic acid<sup>11</sup>, have been known to inhibit the tryptic hydrolysis of proteins. The sensitivity of these inhibitors to ionic strength suggests that electrostatic interactions are of significance.
